All discones are the "same style antenna" (duh) ;)

The difference is in the lowest frequency that they will cover. Most
will go up to 10 times the lowest frequency as their highest frequency.

I have two of the Radio Scrap models - which are really just good for
108 Mhz up. They use a vertical whip to extend the low frequencies down
to the 6 meter band but in these frequencies, you are using a narrowly
tuned vertical whip - NOT the discone part of the antenna (the discone
is actually working as a ground plane in this frequency band.

I have just verified this with an MFJ-259 antenna analyzer. There is a
sharp dip in the SWR at around 50 Mhz (a good thing) and then it is shit
- above and below until about 105 Mhz where the SWR drops below 2:1 and
then stays there as high as the meter will read (170 Mhz).

Other factors with other discones would be more power handling and a
"TRUE" low frequency tuning down to 30 Mhz or below - I've seen an old
Army model at a hamfest that was around 6 ft tall (sitting on it's camo
green skirt radials).

Keep in mind that all discones are "negative gain antennas". You'll
actually lose a dB or two over a dipole tuned for a partical band. It's
that gain vs. bandwidth thing again.

They do make really nice receiving antennas with an amplifier in line.
I used one of mine for TV reception for a few months and was supprised
at the relatively small amount of ghosting for an omni.

Good luck.

That's not exactly true.

You do raise (or lower) the center cond. and shield together to tune for
lowest SWR but the height (you quoted 1.5") is kind of ambiguous as
frequency of operation is not known. You can make J-poles over a wide
range of frequencies and bands (amateur or others). Once the lowest SWR
is achieved, tune (crop) the long element (radiator)for the desired
frequency.

Jim, have you tried laying your antenna along the bottom of straight trench about 18" deep. It will be at least 10dB quieter and well worth the hard labour if its quietness you are looking for. Double-screened coax works even better especially when Nichrome wire is used for the inner conductor.

A peaceful and prosperous New Year to all.

Reg.

but they are allowed almost everywhere, and for the most part cars must yeild to them. try to take a car on a horse trail and see what happens to you! try some vhf contesting some time and watch what happens when you can't quite copy that weak signal on ssb, quite often the will switch to cw to finish the contact... and that is in bands that no-code techs have had access to for years! it would be a real bummer to not allow the simplest form of communication on some bands or parts of bands... it almost always makes a good backup when you can't get through on voice.

>

don't tell the thousands of operators who participate in various cw operating events and contests!

>
> Face it! It`s mostly over. Too many cell phones are around in most
> emergencies for a ham to be indispensable. Anyone can use wireless with
> no license, just pay the monthly fee.

so, go ahead, pay your fee and take what you get. just don't come to my area, your cell phone won't work most of the time. and let one cell tower go down from a storm and it won't work for quite a large area. and i'm sure you won't raise anyone on those new family radios unless you bring along someone to talk to. you might get lucky finding someone in skipland on a cb to talk to.

cw is still useful and worthy of protection on the bands. it is often used where signals are too weak for other modes. it also allows a higher concentration of stations per khz than ssb... tune through the bottom 5khz of

20m during a contest and count how many stations are calling cq, then try to imagine that many calling cq on ssb in the same bandwidth! i will agree with anyone who wants to expand the phone bands, but i still think there is a need for cw only segments on all bands.

horsemanship is also a necessary skill for not only 'cowboys' who still use them in rough terrain, but also for law enforcement in many cities. just try to touch a police horse and see where it lands you.

Yes, this is the 2 or 3% Ag solder I mentioned in an earlier post.
Without the small amount of silver, the metalization on the ceramic
terminal strips would dissolve in the solder, and would be gone from the
strips the first or second time you soldered them. But the silver has
only a small effect on the melting point. Sn63/Pb37 solder is turns
solid and liquid at 183 degrees C; Sn62/Pb36/Ag02 turns solid at 179 and
liquid at 189.

Hi Chip--

Got your E-mail--and I see it's also posted on here. I presume you are saying that you or Phil Salkind (writing on your fractenna account) did not compose the line:

>Not all of us hams are 300 pound-grizzly adams-- loner- man mountains who go and shoot people<

...and that someone else writing on a totally different account originated that line. If that is the case (and the archive will show it), then--of course--I stand corrected and apologize publicly for making the wrong attribution. It's easy to miscount arrows in posts containing multiple entries, and perhaps I did that. Meanwhile, I'll be sure to check the archive and confirm who DID write that dispicable line so I can go chide them instead.

>This is your last chance to just DROP ME from your repertoire of people to harrass. Tomorrow is more than just another day.<

If you must continue threatening me and others on the NG, then for crying out loud, please spell "harass" correctly.

>Rick--JUST--FOCUS--ON SOMETHING--ELSE==> NOT me.<

The focus of my editorial comment was, of course, on Mr. McDermott, his situation, and a very unfortunate stereotypical comment SOMEBODY wrote about large unmarried people wearing beards. If you or Phil (writing on your AOL account) didn't write it, then you have, once again, my sincere apology for suggesting you did.

Pascal, the most effective groundplane is a system of
shallow-buried radial wires of random length.

You may find program ENDFEED interesting. This will allow
you to model a vertical antenna (set the length of the
horizontal top section to zero) above any number of radials
of any length. It will also compute the L and C component
values for an L or T-network matching unit to 50 ohms to
enable the antenna to be used on other than the 1/4-wave
resonant frequency. Or you may elect to use a 3/8ths wave
vertical on 14 MHz.

Download program ENDFEED from the website below in a few
seconds. Not zipped up. Run immediately.

> . . .

I'm well acquainted with Chip's public pronouncements of what will happen legally.

For the benefit of people who haven't been following Chip's antics -- In the latter part of 2000, Chip (first as a representative and officer of Fractenna, Inc. and later apparently representing only himself) posted far and wide (multiple postings on multiple newsgroups and mailing lists) false and unsubstantiated accusations that I had committed piracy and had appropriated material for which Fractenna, Inc. or he owned the copyright. In these postings, he flatly stated that he would take legal action against me, with various deadlines in 2000. Several times he stated positively that he would send me a formal letter to initiate legal action. Later, he stated that the letter had been sent. (This can be easily be verified with a deja search.)

All the deadlines have come and gone. The letter he or his alleged lawyer allegedly sent never arrived. (I'm franky disappointed. I was looking forward to it.)

His threats are empty. He freely slanders others but is constantly accusing others of slandering him and darkly threatening legal action. He doesn't tell the truth.

One thing he really does seem to have followed through on, though, is to hire private investigators to dig up dirt on people he has a dislike for. I'm sure I'm in this category, so I assume he's had a PI checking up on me. If so, can I get a copy of the report? There are a few periods in my past that are awfully vague. . .

Relax, ignore him, and have a better year for it.

Chip, you really need help. I hope you can see your way clear to seek it out in the coming year.

Rick:

Heh, heh. I heartily support your last contention. It's dammed hard to make a profit serving the amateur radio market!

Being engaged in the commercial "for profit" electronics and communications business for the last xx years or so... I can readily testify that in comparison to the commercial possibilities... [cfr Cisco Systems, et al... listed on NASDAQ]...

Serving the amateur radio marketplace with either equipment or publications is not an attractive business!

I often shudder when I hear folks saying that some of our hobby's manufacturers and publishers are ripping us off!

Heh, heh. Even though I could do that, by choice I participate in the far more lucrative professional commercial markets.

Take it from me, no one, repeat no one... is getting rich serving the amateur radio community. The volumes are far too small, and the willingness to pay is far too low!

Especially considering that one can make "real money" serving other areas of the electronics and communications markets using basically the same technical and business qualifications as one needs to serve the amateur market.

For those so-called, "for profit" organizations currently continuing to serve our hobby community, I say...

THANKS... and well done for what is essentially a labor of love. Keep it up, and I for one will continue to try to support y'all with frequent purchases...

-Peter K1PO

I have worked dozens of stations on CW on 2 meter EME. I have *one* SSB contact; (W5UN) of Mighty Big Antenna fame. With the "Obsolete" mode I can communicate, with the here-and-now mode, I can't. This is progress?

I live 5 miles (airline) from a major interstate highway (I-10, exit 248) off ramp. My wife and I each have analog cell phones and I was shopping for a digital replacement for her for Christmas. I figured to get some included long distance minutes to offset the landline charges. I talked to the service technician at Alltel (formerly Cellular One) about service in my area and he laughted and told me I better not give up the wired service. I can sometimes make a cell phone call from here (and pay roaming charges) and sometimes not. If it rains (yes it does rain in Tucson) I can expect poor to non-existent wired telephone service. Please tell me how in an emergency any amount of money can overcome this situation.

Safety Factors, heh, heh:

If such conservative safety factors as we find in the EMI/RFI world today now, were applied to other areas of human endeavor, why then...

Airplanes would not be able to fly, all would be grounded...

Rivers would not be crossed by bridges, all bridges would be declared unsafe...

Automobiles would not be allowed on the roads...

We would all have to raise our own produce, for the grocery stores would not be allowed to sell us commercially produced vegetables...

etc... etc...

Face it... those RFI/EMI/EMC standards are a scaremonger's dream.... let's all try to work to set them to be more realistic!!!

I recall that my brother bought a brand new Mercedes Benz sedan in
1965 with a deisel engine, air conditioning and a Becker-Mexico stereo
for $4,500.

The first Ferrari GTO, from the Sixties, sold, new, for $14,500.

Anybody recall what a Collins S-line sold for?

My rule of thumb use to be that a car cost 1/2 the annual salary and a house was twice the annual salary. Unfortunately, I I just learned that is out of wack, at least after visiting my daughter who lives in the (far) eastern suburbs of SF, CA. They paid a nearly a third of a million bucks for a stucco-box tract house on a postage stamp sized lot.

My mother-in-law gave me a pullover shirt for Christmas that still had an $80 price tag on it. I remember when 80 bucks was my clothing allowance for a year.

BTW, the old gal also gave me 10 years worth of "QST View" CDs that cost $80 plus nearly $30 in shipping charges to get them to me by Christmas. My daughter ordered some too but didn't pay enough shipping charges to get them here before sometime in the next millennium.

Here is a disappointment and a perceived lack of value. The images are pretty poor and the reader/indexer is real clunky. But I'm freeing up shelf space. Might even have room for a new Handbook.

For me to place any faith in the standards, I'd need to see the criteria for the studies, the unprocessed results, and the detailed methods used to both get the data and how it was processed.

Having any group tell me "we did a study and this is our recommendation" had no more validity than had my neighbor told me that every time he uses his cell phone he gets a headache so there must be a connection.

I've spent too many years working with corporations and labs to place much faith in "new studies" where there are no existing and proven standards.

So, all I can say is that if some one asks me if RF exposure can be dangerous I'd have to say yes, but...The level at which is becomes a problem has been determined by methods that I view as shaky at best. Meaning I have no idea as to what level it becomes dangerous. That is why I believe there is such a range between the two allowable levels. I sincerely do not believe that as of yet, industry knows where it does become dangerous. They only have a rough idea.

For instance using a 5 Watt HT with the antenna only an inch or two from a persons face is not considered dangerous as the time is limited, but the field strength is orders of magnitude greater than we get from running the legal limit into a large VHF array.

As to the limited exposure, it is not all that uncommon for a user to spend enough time making 50% (2 min on and 2 min off) transmissions, to end up with an ht almost too hot to hold and a dead battery in short order.

Given what little I've seen of the studies, I have to view their results as antidotal rather than complete, objective, and comprehensive.

At one time it was not a bad buisness, but that was prior to 1980.

In the 60s and early 70s it was apretty good business, but from the mid 70s
it was a steep down hill slide.

Back in those days you could take a trailer load of gear to a swap and go
home with a lot of cash. People paid with the long green, not checks or
credit cards and not much was on credit.

Many a time I took all I could to a swap, or convention and brought home
only cash. The problem with the bigger swaps and conventions was being able
to take "enough" to last through the day as we'd usually run dry shortly
past noon.

Now days, by shortly past noon, every one has gone home.
>
> Being engaged in the commercial "for profit" electronics and
communications
> business for the last xx years or so... I can readily testify that in

al...
> listed on NASDAQ]...

True, but only a tiny percentage are the Ciscos of the world.

I found that consulting in specialized areas can be extremely lucrative,
IF the individual is willing to put in the hours and days and weeks and
months...

Working in computers and Laboratory Information Management Systems (LIMS)
for the medical industry (with FDA Valadation) in particular is almost as
specialized as programming directly in machine code. Man! Talk about
documentation and change control <:-))

Compareing these jobs with amateur radio sales and service is almost
impossible. It's not that they are not in the same league, they are in a
different world.

The only thing they have in common is that they require dedication and long, very long hours. Often 7 days a week and little time for yourself.

There the simularity ends with one almost requiring a second job and the other paying near the top of the individual pay scales.

You didn't really expect to get away with such a piece of non-accuracy
did you Rich? :-) You spoke as a ham who truly has no knowledge or
experience regarding radiotelegraphy. The latter I can understand, the
first I cannot, given the length or your tenure in radio.
There are times when nothing else is applicable or workable. Someday it
may be otherwise, or maybe not. But not yet. It doesn't all depend on
just the current state of technology.

73 anyway, Dick W0EX

Not exactly "on topic" but going back a helluva lot of years the only trap antenna I ever owned and used was an old Cush 10/15 "Duobander" which was installed 80 ft AGL and I didn't take a back seat to ANYBODY in the dx contests or pileups on 10 & 15, the thing kicked some serious butt with nothing more than an SB-200. I pulled it down after 30 years in the air in a polluted heavy industrial area a couple years ago. The four driven element thermoset plastic standoff insulators should be replaced, otherwise it's good to go for another thirty.

ok guys, i am not kidding. this antenna works great even though everyone says it wont work at all. it is for receive only and is laid right on the ground. it is very low noise (even if it is low gain i need all the noise rejection i can get) i use it for listening to shortwave with my portable radio. in my circumstance it is far superior than several "better" antennas that i have available, and it is very convenient to lay out anywhere its needed. i just thought i would run some ideas past you, i didnt mean to spill any "snake oil"

The problem with the 4815 probe is that it uses very difficult to obtain p
channel FETs.
The current model that Agilent makes has a similar probe, only with n
channel FETs.
In any event, you would be FAR better off rebuilding an existing probe,
rather than
trying to invent your own or build a copy of the Agilent one.

If anything, the 4815 in now MORE exotic than when it was in production both
due
to obsolete thru hole parts and the fact that there are very few engineeers
around who
understand analog instruments these days. Even at Agilent, few engineers
are versed
in such theory.

ok, ignore the snake for now. someone take me to school on making an artificial ground or a counterpoise. does it have any relationship in size or length to the antenna element? is one wire all thats needed or is several wires laid out like radials more effective? what can be expected of the effectiveness of this scheme as compared to a good earth ground rod? and what is the comparison of a random wire with a counterpoise as compared to an equal amount of wire in a balanced format such as a dipole?

Didn't expect so many people to jump in with other ideas. All we did was insert a Radio Shack 273-1374 as an isolation transformer between the sound card inout and rig audio output. The noise problem went away, and we never bothered to "Engineer" it to death.

Dick Carrol wrote:
"There are times when nothing else is applicable or workable." (Other than Morse, I suppose.)

We can choose to ignore better digital modes, but they abound and they are more efficient and effective than Morse.

Telegraph. The word implies a written or drawn item sent or received over a long distance. This is what Morse intended. He was seeking a system which recorded its output on paper. As I recall the story, his father-in-law was funding development of the telegraph and the man with the money persuaded Morse to go to market with what was already working, and not wait for perfection of the printed message development. It seems this was a case of father knows best.

Telex and Teletype came later. There are many other digital data transmission codes and architectures. Most beat Morse efficiency by starting with code elements of equal lengths for the mark and space (zero and one) durations.
Effectiveness is improved by error detection and correction along with automatic retransmission of garbled reception segments. Data transmission rates can be automatically adjusted to fit the condition of the transmission medium so as to optimize transmission efficiency.
Trying to use Morse to compete with modern data transmission is equivalent to showing up at a gun fight with a knife.

There was an American Cavalry General who advised his troops to dismount should their horse be shot from under them. Seems the coders have been beating a dead horse for years.

Best regards, Richard Harrison, KB5WZI

Mary expressed a very human and heartfelt concern and empathy. I , for one, do not find it in bad taste to have some here reminded of the frailty of human life and the tragedy of its loss, especially all too soon and all too sudden and all so pointless.

One of the victims lived in Belmont-- a friend of a friend. His funeral was at St Joseph's Church. The town is in shock.

You have no idea what effect this has had in the Boston area.

I would agree with another post about the Diamond having a more robust construction. I have owned 4 Radio Shack Discones and the elements are all a little loose. If you want to impress the troops, get a Discone from Kreco (www.krecoantennas.com). I have used them for over 20 years and they seem to be THE standard in commercial Discones.

Sorry, Chip. You've used up what remaining credibility you had. Too many "last opportunities" have come and gone, and your threatened legal actions are nothing but bluster.

I do not have, nor have I ever had, any material on my web site for which you hold the copyright. If you did have the fortitude to sue me, I'd be glad to let you try to prove otherwise. But you don't.

Roy Lewallen, W7EL

I had the *old* (about 10 years ago) Radio Shack discone that had no vertical element. After about 2 yrs on a mast in upstate NY year round I was missing a few elements, others were bent, but it still worked pretty well for a $60 antenna.

About 8 months ago I put a Diamond J-130 in the attic of my new home and connected it (RG-6) to my Pro-2005. Compared to the extendable whip, this antenna is doing a great job. Even while assembling the antenna (in the kitchen when my wife came home at about the half way point), I could tell there was a big difference - more than just a vertical element! It's a solid antenna that I would not hesitate to put out in the weather if not for the objection of my wife.

It comes down to cost. If money isn't an object and you want something that will last for a while, the Diamond is the way to go. If you are on a budget and not real serious about adding this type of antenna, go for the Radio Shack discone, or even the smaller antenna they offer if you only need RX. I think that one is about $30.

I just wanted to thank all who replied to this thread, it has been a great help to me .

I have a question pertaining to gray's reply :

" I also float the radio and
anything connected to it by using an AC ground lifter with the ground terminal unconnected."

did he mean AC ground filter? would this be like an isolation transformer, or a filter consisting of a capacitor like in a power supply, or a ground fault breaker?
did he mean leaving unconnected, the separate ground wire, the one that usually is found hanging out the back, along with the antanna wire ? or the common wire, meaning the wire that is connected to ground (not the third prong)

this is of great interest to me in my plans, as I do get alot of noise from nearby computers, tv's motors etc.

I read another comment in another thread about connecting to more than one radio, someone suggested that it was a bad idea to have more than one connected to the same antanna, that the signal would be reduced by half if it were connected to more than one. is this true? I was thinking of using a piece of cablevision wire, and outlets to run to two or three locations, just because it would be neat and the connectors are readily available. perhaps I should include a selector switch if doing so?

I had the old RS discone, too. They didn't have a top vertical element
but the 5/16" threaded "nub" is there for one. I've just built a
vertical element for it - out of PVC and some all thread. It hasn't
gone out in the wind yet.

Rich, you just don't understand, and that is something that I *can* understand since you haven't experienced working Morse, at least to any extent.
There is a letter to the editor in the new issue of QST which illustrates what I'm speaking of. Describing how he'd heard that "CW gets through when other modes can't", the ham said he had finally saw it it action. He was in SSB QSO with a ham friend on 40 meters when the other station faded to where he lost copy and could't tell what was being said at all. At that point he heard the other station on the frequency on CW, weak but readable, sending "3990, 3990". So he switched to 75 meters on 3990 khz and there his friend was, on SSB, and they then completed their contact.
So - what other mode would have accomplished the same thing in the same way? RTTY? PACTOR? CLOVER? SSTV? PSK31? MFSK16? Don't think so. With no preset arrangements that dictate what other mode they should go to, and no time to make them,(even if equal gear was present on both ends) only a quickly implemented, universally understood media could serve. Any other signal that appeared wouldn't have been understood and copied. Certainly it wasn't anything earthshaking, just a clear illustration of one of the unique characteristics of radiotelegraph communications. When it is widely known it can quickly and easily be used. No other mode is so elegant in its simplicity and flexibility.
There's no question that other modes are more efficient and for most uses in most cases, better suited. That's progress. But progress doesn't change the attributes of CW.

Phil,

What power level do you want to use? For QRP, a home-made solenoid or toroid inductor mounted on a multi-pole rotary switch, and tuned as an L-match with a receiving capacitor, will tune almost any wire you cam throw out the window, within reason. With two caps, as a pi-match, this is also suitable when you need only tune out small mismatches or reactances even at the 100 watt level. The size for such a tuner will perhaps run around 5 by 8 by 8 cm. A higher voltage output capacitor will of course be needed at the 100 watt level with high-impedance antennas, and increases the size. However, using transmission-line transformers to match impedance, and coil and cap to match only reactance, might shrink the capacitor required.

Cortland

Sorry that was not directed at anyone in particular Wes,
just one of those generalities.
Only the names have been changed to protect the innocent.
I thought it was the three wise men that came bearing gifts. ;)

Of course you are quite correct about my slack use of the words
"Silver-Solder", I'm afraid you'll have to put that down to the common usage
of that time, a sort of jargon/ shorthand used by insiders and taken to mean
"Silver Baring Solder".

Thanks Bill nice informative post,

> As to the 'Lead poisoning', I may have been more at risk than you- at
> one time- MANY years ago, I used white lead in some activities.
> We were very ignorant, and I now find that scary.

Well Bill you'll have an excuse, unlike me a bit ecentric,
(runs in the family I'm afraid), but the less charitable might say,
"just plain barmy". ;)
As for being ignorant back then, what about the open wide mouthed bottles of
Benzine and Carbon Tet that used to adorne our work benches.
The Certification that NASA required was for all Technical personelle even
if they rarely did any bench work. This happened one day aftera conversation
with my Boss and a few other engineers. I casually said that although I had
been permitted to design things in the aerospace Industry they were wise
enough to not lket me loose with a soldering Iron even thoughh I had passed
the RAF Workshops p[ractices with flying colours. About three weeks elapsed
and all personell were sent on courses a few at a time for a week each. It
made a nice break from the inevitable shift work that goes along with
tracking spacecraft in interplanetary space.

Mr. Lewallen--

You will be receiving two legal notices.

The first concerns your pirating and of copyright material held by me and the second is for libel and malicious harrassment.

Your assertion that I have NO credibility is a direct and focused public attack, malicious libel to undermine my abililty to practice in the applied physics field, specifically in antenna design and electromagnetics.

You will be served with legal and public notices within the next two weeks, unless you now STOP ALL malicious libel and harrassment and REMOVE the MI2 file from your commercial web site.

Nathan Cohen, Ph.D.

Fracky- How is your lawyer going to file against Lewallen, when he is busy preparing the suit against me, for similar charges, that you promised in off-NG posts to me. I would appreciate learning the name of your lawyer (not Kaufmann, surely) so I can streamline the response of my team.
Frankly, we are looking forward to the action, because we stand to win $$$ in our counter suit. The evidence is pretty clear, and we only need a real filing on your part to proceed.

Have a good year- Hope this helps.

I've done the same thing that guy did, switching to CW when SSB failed. If I had never known Morse code, would my life have turned out any differently? Not appreciably. If Morse code had not been fun for me, would it have been worth it over the past 50 years? Nope.

I've had PACTOR II QSOs when CW QSOs would have been impossible. That's not earthshaking either. It's simply freedom of choice of modes within amateur radio. Seems the argument is a lot like abortion - either pro-choice or pro-Morse with the pro-Morse side relying primarily on emotions.

Counterpoise:

Another name for "the other half of the antenna".

As "The Bard" wrote centuries ago...

"A rose by any other name".

A counterpoise can be made of approximately 1/4 electrical wave of wire, or of some lumped elements, or some, or any combination thereof. It should really be placed as high as possible since... it will radiate. Many just lay it "on the ground".

Heh, heh. But anything works if it gets you "on the air".

By whatever means, just make the counterpoise, electrically speaking, as much like the "missing" half of the antenna as you can.

All else is a compromise!

Dick Carroll wrote:
"He was in SSB QSO with a ham friend on 40 meters when the other station faded to where he lost copy and couldn`t tell what was being said at all. At that point he heard the other station on the frequency on CW, weak but readable, sending "3990, 3990".

Interesting because it is atypical. These guys just waited too long to make their move. It`s their fault they didn`t recognize deteriorating band conditions and make their move sooner.

First, losing contact is usually no big deal because ham conversations are limited to trivia by the rules except for emergency traffic.

Second, fading is usually a come and go situation during the transitional period until a more stable open or closed band period is reached. There are usually opportunities to agree on where to go to continue the conversation, without ever resorting to a different mode.

If maintaining contact is important to the operators, they can prearrange a fall-back strategy for a complete cover-up or fade-out.

Best regards, Richard Harrison, KB5WZI

> points of diminishing returns.
```

Which the data confirms. What he might have given in the 1930s for some of
our modern precision instrumentation. Though the experimenters rigor seems
to have improved inversly to the precision of the available instrumentation.
I guess we have all become a little blas .

```
> From one of Laport`s graphs, here are data for a 1/4-wave vertical
> antenna at 3 MHz using different numbers of 0.412-wavelength radials.
> Field strengths in millivolts per meter were measured at one mile.
>
> n mv
> 2 120
> 15 155
> 30 170
> 60 180
> 113 185

Very interesting looking at those figures in a slightly different way could
be useful as to why all observers experience was not identical.

| | improvement |
n | signal | inc. | total |
2 | 120 mV | 0.0 dB | 0.0 dB |
15 | 155 mV | 2.2 dB | 2.2 dB |
30 | 170 mV | 0.8 dB | 3.0 dB |
60 | 180 mV | 0.5 dB | 3.5 dB |
```

113 | 185 mV | 0.2 dB | 3.8 dB |

Obviously the observer that increased the number of radials from the basic two current sink to 15, was immediately rewarded by observing an increase of 2.2 dB

But as the process continues the observed improvement starts to diminish below the precision of measurement.

How recently was this experiment repeated using modern instrumentation?

Are you suggesting that the tower should be tiltable and tipped in a certain
manner to obtain preferential radiation in a given direction at a given
angle? (where the Dx lurks)

Jim wrote:
"Is one wire all that is needed or is several wires laid out like
radials more effective?"

Perhaps the difference between a "radiating" wire and a counterpoise is that a radiating wire may induce a current in a receiving antenna.

Suppose you have a VHF ground plane (GP) transmitting antenna up high. A receiving antenna may be excited by the vertical element of the GP, but not by the radials of the transmitting antenna. Why? Because the displacement current in the transmitting GP is between the vertical and horizontal elements of the GP. It flows into and out of the various radials at the same times. That is, current is towards or away from the drivepoint simultaneously in all the radials. Seen from a distant vertical receiving antenna, the effects of various radial currents cancel. Currents from the right cancel currents from the left in producing external fields.

Replace the GP transmitting antenna with a vertical dipole. The lower half of the dipole is a radiating element and not a counterpoise. Displacement current flows away from one terminal of the feedpoint while flowing into the other feedpoint terminal. That means current flows in the same direction in both halves of the dipole. In the vertical dipole, the current in both halves is either up or down simultaneously. Seen from a distance, it could just as well be an end-fed wire. Both halves of the center-fed dipole equally contribute to the radiation total.

Happy New Year!

Jim,

I use one as well and they do work. The main discussion on them seems to revolve around a couple of points:

1) Do you terminate the far end or short it ? This probably changes the directional properties of the antenna and obviously changes it's impedance.

2) Do you break the shield at some point ? This is by analogy with a magnetic loop and I have not seen any real data on it's advantages.

3) Real good coax or crummy stuff ? Aluminum wall hardline is one extreme, foil jacket LAN coax is probably the other extreme. One group seems to like the "leaky line" effect of the foil jacket the other group seems to like the improved shielding.

Right now I have mine terminated, with an unbroken shield using fairly good coax. Next up will be a couple of hundred feet of hardline ....

Enjoy!

Bob

I know this is the so-called digital age and code is old-fashioned, but it still is fun to fool around with.
A lot of you have a great fear of learning code. I really can't understand why. It doesn't brother me that they did away with it on tests and I don't begrudge any of you for not wanting to learn it, that's your business. I have been a ham for over 20 years and I enjoy fooling around with it. I am still not real good at it, but I think it's fun to connect with someone out in Tim Buckto who's running 2 watts. I don't care for the speed jockeys out there who try to impress us all with their lighting speed. They don't impress me at all, and all they are doing is showing off when they contact you. I stick to the Novice bands when I use code.
At your convenience, you ought to think about learning it. It really is fun to experiment with it. There are translating programs available that will print out on the code you receive your PC monitor.
My 2 cents worth on this ongoing code controversy. 73's - Pete

Couple of things to try.

You don't state whether or not you have a rotator or where you the the stations are located. Either install a rotator or rotate the antenna to improve this channel. You will have to determine the sacrifice for the other channels.

Try a mast mounted pre-amp, but go to a TV Parts and supply house. The AMPs will be better quality than Radio Shack, but Radio Shacks' are OK. This is less massive to install than a larger antenna.

Last, if possible, bump it up another 5-10 feet (1.5-3 meters). Sometimes additional height will help. Again, I don't know if you are in a deed restrict development limiting you to 6 feet above the tallest peak of the house.(FCC preemption)

Finally try a better antenna. But be careful and have help or have it done professionally. Standing on a roof and trying to manage a bulky antenna can be more than one person can handle.

Good luck and 73's

Dennis WB3KUM/9

Source record: 173348

The "snake" works as well as any wire laying on the ground,
and sometimes that's better at defeating noise problems
than any conventional antenna you might have available.

There's nothing magical about it.

It doesn't need the terminating resistor. It doesn't need to be made
of coax. Just lay an insulated wire in the grass in a straight line
as long as possible. Keep it as far away from the transmit antenna
and other vertical antennas as possible.

If long enough, it acts as a "very low bi-directional Beverage".
It will provide far weaker signals to the receiver than a
Beverage which is off the ground 3 to 12 feet.

When my Beverages are down for the season, I have laid
such a wire on the grass for a DXpedition and had it make
the difference between hearing and not hearing the DX.

In low band recieiving, more receiving antennas is better. Try
everything. Sometimes the 10m yagi will receive a 160m
station better than the 160m transmit antenna or a short Beverage.

to the best of my knowledge, all of about 6 months worth now, a counterpoise for a vertical antenna is an attempt to "convince" the antennait has a vehicle underneath it, as a car is a counterpoise on a cb antenna. the study book "Now You're Talking" has the discussion that i found most benneficial.

A short snake story:

A couple of months ago I put up a new Beverage antenna and went into the shack to check it
out. It didn't seem to work normally, but in listening around, I got really great reception on
one particular station compared to the 90 foot vertical. Turns out the coax was shorted at
the far end; I had accidentally created a snake antenna! I later determined that by lowering
my Beverage antennas to 2 feet (instead of 10 feet) I could get snake like performance
consistently, but without the extremely low signal levels of the snake. As other posters
have pointed out, there is nothing magic about coax and you could just as well use hook up
wire to make a snake.

Chip--

I checked the archives. The "mountain man" statement was, in fact, authored by fractenna and posted on the 28th. Of course, you knew that all along!

Perhaps Suskind wrote it, perhaps you wrote it, and perhaps your dog wrote it. It really doesn't matter because there's no way you can prove to me or anyone else you weren't the real author. This ambiguity has less to do your voracity than with the irresponsible way you manage your fractenna account.

Suppose Suskind DID compose it, as you may claim? Even if true, did you not offer, pay for, and condone his use of your account, company name, and keyboard without regard for content or restriction?

The fact is, without your complicity, encouragement, and possibly even direct authorship, the "mountain man" message would never have been posted on this newsgroup in association with you. In the end, you were ultimately responsible for its appearence, you should have know better, you DO know better, and I retract nothing.

Mr. McDermott's story should warn us all that persuing an adversarial solution to set things right most often yields bitter fruit for the person who persues it. In the new year, you might wish to reflect upon Roy's sage advice...and heed it.

73 and Happy New Year

So then you support criticism of CW on "the facts" when the speaker
really doesn't know enough about it nor have the experience to know how
it really works? That surely is an odd position for one who purports to
be a scientist who deals in facts.
No one has said that people who don't like code must use it. Not even
the FCC. What we do insist on is that they not assert as fact positions
which are not factual. When the assertion is made that just because CW
is old and better modes are often available, that no one ever needs it
or finds it useful for real, live communications, that is simply not
factual. And not just by amateurs.
The Interstate Police Communications Network used HF radiotelgraphy
into the early 70's for longhaul traffic handling even though RTTY had
been around for decades. I was a part of the technical crew that removed
the CW gear from the State HQ station in 1975 after it was finally
completely phased out. Even though our state had not used it internally
since 1965, we still relayed for other states which did, into the early
70's. If anyone is interested references are available
If you hadn't noticed, there has been an awful lot of that sort of
criticism taking place in recent years, aided and abetted by the likes
of you. I guess you've got to protect your professionmal reputation as a
techie, if you were viewed by your peers as a supporter of "Luddite"
systems it just wouldn't do your technical reputation much good. I can
understand that.
But facts are facts.

Yep, and if they haven't done that, and most ham contacts have not made those prearrangements since they're rarely needed, it sure is beneficial to be able to easily fall back on a mode that handily and quickly fills the need. And, of course, if it can be used at all it can be used for serious things, too. One doesn't always get to choose he mode or conditions under which one operates.
If someone calls a SSB station using CW with urgent traffic should he just ignore it since he didn't choose the mode?
Will CW ever "save the day"? Probably not, for sure not if all hams abandon learning it. But to deny its communications potential just because later modes exist is to ignore reality. Cessnas still play a transportation role even though 747's haul the big numbers.

Correction, Rich. It was ARRL founder H P Maxim's father who invented a machine gun, intending to make a weapon so terrible that war would be banned. As if.

instrumentation?"

I don`t know.

Richard Clark is probably as well qualified as anyone recently posting to this NG on the subject of measurements and may comment on probable accuracy the old guys got with the instrumentation available at the time. He surely knows a lot more than I do.

Logically, during the last 70 years, many would have verified the data or challenged them. That the work of Brown, Lewis, and Epstein has not been superseded by broadcasters trying to save a dollar, or make mischief for their competitors, says something about its accuracy.

Happy New Year.

Best regards, Richard Harrison, KB5WZI

You might try a yagi type of antenna. I used an eight bay years ago and
the gain characteristics on uhf are better with the yagi. The more
elements the better the gain. It is also more directional. A good preamp
with a LOW noise factor is also essential. Less than 3db would ba a good
choice as is a good quality double shield RG6U coax. All this leaves
Radio schlock COMPLETELY out of the picture. Winegard makes some
excellent commmercial antenna equipment.

> is several wires laid out like radials more effective?

Here's the way I see it in lay language, not engineeringese.
The best possible counterpoise for a 1/4 wave vertical antenna would be
a
metallic disk a halfwave in diameter with the vertical element mounted
exactlhy in the center. From that, it goes downhill, but not fast at
all. Broadcasters use 260 quarterwavelength radials, but experts posting
here say that less than half that meny would do just as well, and the
extras are just insurance against
loss due to breakage, corrosion etc. When you've seen an AM BC radial
field that has been there for years, you see what they mean. Corrosian
is a way of life.
As a practical matter, most hams use four quarter wave radials. More is
better. Some investigators have said that more, shorter ones will work
nearly as well. Do the best you reasonably can.
Bottom line, install the best ground plane you can considering your
site, budget, interest and communications goals.

what can be
> expected of the effectiveness of this scheme as compared to a good earth
> ground rod?

It is surprising how nany hams sjust drive a ground rod at the base of
their vertical and go on the air with good success. NOT with maximixed
field strength.

and what is the comparison of a random wire with a
> counterpoise as compared to an equal amount of wire in a balanced format
> such as a dipole?

In my camping rig I use a 60 ft random wire, never above about 10 feet
high, tuned with an automatic tuner and use a 40 foot piece of magnet
wire lying on the ground for the counterpoise. (I have hooked to the
frame of the motorhome but got to thinking about the 40 gallons of
gasoline in the tank, and decided against it since it's not possible to
know just what voltages develop where, particularly with a
frequency-agile allband system).
I have no problem at all making all the contacts I want, in fact I get
reports comparible with my 50 ft dipoles I use at home.

I believe it. Signal-to-noise ratio is much more important in your
circumstamces that signal levels, if there is enough signal to receive.
Plainly the snake antenna gives you an attractive s/n ratio.

Dick

Go to Home depot (or equvalent) and get three screw anchors, the sort
used to tie kids swing sets to the ground. They screw into the ground
and should do the job.

Don: I also have the A3S and it has been up for several years. It
does fine, use it on 20, 15, and 10M. Consistently provides 1-3 S
units better signal than the trapped dipoles I also have for same
bands. Haven't checked SWR in so many years I can't comment
on that (guess it's time to check them). Antenna is only up about
45 feet but country count stands at 275, mostly worked on A3S.

Just for the record, Hiram Percy made contributions to explosives technology, too. I had forgotten that he was a MIT fellow!

"Hiram Percy Maxim, 1869ï¿½1936, son of Sir Hiram, was born in Brooklyn, N.Y., and remained in the United States. After graduation from the Massachusetts Institute of Technology, he held many positions as a mechanical engineer and created several inventions, among them an automobile. The most spectacular was the Maxim silencer for explosive weapons (1908), but perhaps more useful were silencers for gasoline engines and the like." The Columbia Encyclopedia: Sixth Edition. 2000
http://www.bartleby.com/65/ma/Maxim.html

All the best in the New Year, Dr. Cohen.

Gary7SLL wrote:
"Are you suggesting that the tower should be tiltable and tipped in a certain manner to obtain preferential radiation at a certain angle?"

Don`t go tilting towers. It isn`t practical.

I was just noting that low-angle radiation used a reflection point farther from the tower than high-angle radiation needs. I agree with other posters that radial lengths are not usually extended to make a good reflector for low-angle rays. It isn`t much needed by the low-angle ray because a more grazing incidence produces a better reflection than a sharply angled strike on the reflector.

The way to low radiation angles is tall towers. The way to horizontal directivity is multiple towers.

Happy New Year!

Hi Roy,

This cavalcade of comedy capers continues cavorting ceaselessly.
Cudos.

The only apology necessary is for when you started getting weepy about
not getting love letters from back east (C'Mon now, you don't really
expect they will ever a arrive do you? Oh - I guess that was the
point.). The amusing response was worth the cost of such public
humiliation (you were one-upped even here by Fraudtenna's self
debasement and humiliation about credibility).

We've been regaled by the denial of being a public figure. That too is so obvious it really doesn't require repeating (but leads to an obvious conflict in the claimant in that it is a desire unfufilled - don't cry for him Argentina). But in the best of all possible lights, this lack of public-figure-hood is a blessing in disguise.

Not a public figure? Sure, how else could any "professional" make fraudlent claims (the notorious "protected by patents pending") that his peers would howl at in derision if they were aware? Imagine how goggle-eyed they'd get if they understood he made them within days of the publication of patents that clearly reveal Fraudtenna had no claims coverage for? They would be in all likelihood amazed that someone would offer such a transparent lie. Apparently Fraudtenna barely makes a ripple in the "professional" circles and is thereby protected by anonymity from the exposure of such foolish pronouncements. Of course we get to hear them here with full gusto, but our circle is a small one and hardly the world stage. In other words, we should enjoy these gaffs knowing that responding to them in an amateur venue will hardly injure anyone's "professional" status.

One of the more wry observations here is that across the country libel laws have varied. In some jurisdictions it is a libel to expose the TRUTH, where in other venues it is a libel to state a LIE. Given the extent of this list of "possible legal actions" that "could be" brought (spread across many states), Fraudtenna certainly could pick and choose a venue to satisfy ego. Our amusement comes from the fact that nothing has come of nothing ("King Lear"). Apparently if this were a frustration for Fraudtenna, then the obvious problem would be in the quality of legal advice obtained (this is, of course, simply a presumption - that is, legal advice having been offered, or more importantly, understood). Given the quality of patent work (ego certificates) issued this is doubly damning.

If there are any actions that could be taken to court AND WON, it would be to recover damages for professional disrepute Fraudtenna's lawyers have suffered at the hands of their client.

To others who e-mail me about these abuses, note the following phrase:
>within the next two weeks
may be commonly accepted as being before the 15th of Jan 2001, but typically employed here simply means that there are some two weeks in the future (always true) that come next (again true) but do not necessarily mean what we expect it to mean(SOP).

One such pronouncement that was to inspire me was the prospect that (three months ago) I would be contacted in "the new month." I of course recognized that immediately to mean sometime around Fractember (the "new" month) or Frauduary, but my calendar hasn't caught up to these "new" months yet - and yes, I pine for my love letters too Roy! Oh the bitter pain of broken promises. ;->

All: enjoy the comedy and lower the thermostat.

My brain handles cw in much that exact manner. My error correction is quite good. And I don't even have to drag an extra digi box around with me.

Data
> transmission rates can be automatically adjusted to fit the condition of
> the transmission medium so as to optimize transmission efficiency.

So can cw.

> Trying to use Morse to compete with modern data transmission is

> beating a dead horse for years.

Well, I dunno, All I do is use the mode. I haven't really concerned myself if anyone else uses it or not. All the other modes are pretty old too. AM, SSB, SSTV, RTTY, all are fairly old and arguably lame also. I've tried them all just about, and still go back to CW as my favorite mode when not in a large group of people talking. Why? Cuz it's the funnest mode to use. Here anyway. I hate keyboard radio. Booooorrrrriiiiiinnnnggggg. I tried the rtty, etc, bit on 20m, and almost to put me to sleep. I'd rather work cw any day. Gives me more to do. Working a digi mode is like logging onto the net and getting my e-mail. Yawn....I'll stick with my old desrepit, but "fun" mode. Of course, what anyone else wants to do is up to them, but to say a mode is obsolete when they don't even use it to make a valid comparison, is like

me saying that PSK31 is worthless because I can't decode it by ear. My argument wouldn't really flush either. I've never had a real problems with the lowering of the cw testing standards, because I realize nothing will stay the same and the abilty to use code has become much less important. But when I hear people say code is nearly useless for modern use just because it's old, I have to laugh. I guess we better get rid of all the other old modes too then I guess. AM and SSB would have to be the first to go the way I see it. A horse is only dead when it can't be ridden anymore. There are still alot of people riding that old horse called cw. So it's not close to being dead yet. MK

106. Mini Quad Antenna 10-15-20m UPDATE

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-01 20:05:27 UTC
From: Antenna <antenna@attcanada.net>
Message-ID: <2q546.12855$t3.28101@tor-nn1.netcom.ca>
Source record: 173277

We have completed additional testing and wish to share this data with you.

Unfortunately our independent tester did not get the chance to do his testing, however we have had some extensive contacts and trials in the past month.

Snow, Ice, Winds and several times up and down the rof for demonstrations and still going strong.

Details of the antenna.

This is a true tri-band two elemnet mini-quad antenna on the 10m, 15m and 20m bands. It has a single feed point and no switching is required. It is portable for field trials.

Dimensions.

Open approx. 3.4m x 3.4m with a 2.44m boom (135" x 135" x 96").

Folded approx.30cm x 30cm x 2.44m (12" x 12" x 96")

Wt approx.14kg (30lbs) without crate.

Turning Radius approx. 2.1m (83")

Performance almost identical to a full size quad (details to follow on Web Page).

Availability......Soon!

Price.......To follow.

The antenna is called the BABY BOOMER QUAD by Degen Designs.

Our web page is not yet set up but expect to see soon it at www.degendesigns.com

If you wish to be updated as our product and page comes online please drop me an email at info@degendesigns.com

Regards,

Guenther

I am looking for a Gin-Pole or Gin-Pole bracket to fit a Rohn 45-G. This
does NOT have to be new, it can be used or even home made. If you have such
item, please e-mail me at kb2sin@stny.rr.com
thanks and 73's

Might be a good idea.

I used to copy about 55 wpm in my head, but could only manage about 35 wpm
with a Vibroplex. I was a lot more concise, and careful about what I said,
when using CW as compared with talking.

This newsgroup could use a little more conciseness and carefulness.

Happy New Year!

>Best regards, Richard Harrison, KB5WZI

Hi Richard,

Yah looped me into this one for sure.

Accuracy is not always a function of newer, better, more resolution. In fact these last characteristics are generally indicators of the illusion of a false security.

Techniques rather than equipment count far more for the accuracy of a test. The techniques may have been supplanted with others employing "state of the art" gear, but that doesn't necessarily mean more accuracy either - simply more productivity.

The techniques of yore can be as accurate, or more so than present day methods. The technique of distinguishing 0.2 dB is not that very difficult, even for the tests performed more than 50 years ago. It does call for some ingenuity, but those fellows drew on ingenuity far more than we do now.

The simplest method to achieve accuracy is to employ a transfer standard along with a technique that uses ratios. Almost anyone here can bootstrap themselves into a very accurate measure of nearly any phenomenon by observing this rule. Coming up with that transfer

standard is the real task, but it should be noted that every important measurement that a Ham would be interested in, has a method that was originated more than half a century ago (or even 100 years ago) to an accuracy far in excess of any Ham's expectation.

Hi Rick,

While it may be difficult to come up with these exotic components, the problem should not be one of acquisition, but rather substitution.

There are many OP-AMPs available that could easily replace these components and eclipse their frequency response. Such substitution is not for the faint-of-heart certainly, because those same OP-AMPs could easily turn into free running oscillators if not handled correctly (thus supporting your contention about the difficulty of linear design). I have many designs that employ 60 MHz wide baseband amplifiers with nanowatt sensitivity (using 1 GHz amps) that consume less than 1 square inch of real estate. These designs are now 10 years old, I'm sure that the state of the art would allow me to design ever higher frequency applications (with ever higher chances of loss of stability - but even here advances improve my chances), but perhaps not for the intended application.

I offer substituting OP-AMPs over discrete components exactly for this reason of stability and realizing a useful design. The probe is not a mysterious black box, it is a technical challenge. For an amateur, it is worth the small expenditure of cash (say less than $20) to attempt a kitchen table coupe instead of shelling out (say more than $100) for

instant gratification. Others may say that the $20 approach steeply discounts the worth of my (or their) time - that too is a worthy consideration.

CW has exhausted its communications *potential*. There is nothing
new to be learned about CW. If CW were a serious communications mode,
commercial interests would not have abandoned it. Any ham is free
to learn Morse code and I encourage all hams to do so. It is fun
and may accidentally come in handy some day. In fact, any citizen
is free to learn Morse code. However, this is a free country and it
should be a choice, not a federal regulation. We have too many
federal regulations.

>Fractenna@aol.com is NOT a
person. It is an ADDRESS.<

Fractenna is more than "an address", Chip, it's YOUR address. You pay for it, you control access to it, and you're accountable for it. A crack house is "an address" too, but that doesn't absolve the owner from full responsibility for what goes on there.

>I did NOT make this statement<

At the moment, I don't see how you can prove that.

> I do not, in fact, agree with it;<

If other alleged "persons" using your account are making you look bad and casting doubts on your authenticity, the solution is simple. Change your password and keep it to yourself. That's how the system's supposed to work.

> If I do not receive a retraction from
you, immediately, I will proceed with legal notice<

If you can offer me convincing proof you didn't write it, I'll immediately change my attribution from "Dr. Cohen" to "fractenna". But, a mere "say so" followed up with a nasty threat hardly constitutes reasonable proof, does it?

Since everyone and their dog seems to have access to the fractenna@aol.com
account, you will be hard pressed to PROVE who did, or did not, make
the statement in question.

Seems to me you brought the whole thing on yourself by allowing this
access to the fractenna@aol.com account instead of doing what people with
common sense do; have individual accounts for each individual.

Standard foxhunt/DF stuff: I improvised a dipole and used
the null off the end to find the offending pole. If it was
good enough to track down spies in WW2 it should be good
enough to find bad power line insulators in 2001...

My solution to ground loop problems is to run all the RF
stuff off a battery. YMMV.

Anyone have a design for an interlaced 10 and 15 Yagi that they would be willing to share? I'd like to consolidate some tubing to gain space on the mast for other projects.
All of my efforts seem to model great on 15, but 10 suffers from interaction in EVERY
parameter. I'm not willing to lay out cash for a Force-12 off-the-shelf design. Cheap is better!

Almost the same exact speed and reasons here. I got to about 55-60 wpm,
but couldn't send any faster than that with my bencher paddle. And even
at just 50 wpm with the paddle , I'd be blowing a few mistakes here and
there. I'd get sloppy. It's something you have to do often to keep the
rhythm in your fist timed to what your brain is thinking. Being as most
don't go that fast, you speed down for a while, and then when you go
back to a 50 wpm guy, my timing would be outa whack for a few min. All
the real speed dogs use keyboreds, "pun intended", but I hate those, so
my limit ended up about the same as yours. And I'm slowing sinking year
by year as I work less than I used to. I'm probably only good for 35-40
right now. But I could practice over a weekend "say field day" and jump
right back up. I can go to a field day doing 30 wpm to start, and end up
20 wpm faster by the time I leave. But then it slowly bleeds off again
till next year .:(MK

Can anyone here comment on the compact HF antenna designs at the above web pages? How can the notebook antenna have a high radiation resistance (and thus high efficiency) from 40m to 10m?

How does one figure out the radiation resistance for a particular antenna design?

They can do what they like. I'm not stopping them, or complaining about their choice of modes. Just as long as they don't get on my frequency to do it , that is...g Make sure the frequency is not in use first!

But all that is fairly moot now. Being as the FCC has lowered the cw requirements to the min level as stated by the international regs, I can't see how they are shoving anything down anyones throat. You can get a ticket with no code, and you can get the rest at a speed that is so slow as to be useful in the real world. When the international regs do away with the code, I'm sure the FCC will drop in line real fast. Anyway, for me I never saw any real distinction between code or any other part of the test. "theory". It was just a part of what I had to do to get a ticket. I'm sure some people could do without the theory tests for the same reasons some don't like the code tests. MK

Hi Jim,

Note the outrage:
>> Repeat: I did NOT make this statement. If I do not receive a retraction from
>> you, immediately, I will proceed with legal notice, and then whatever else is
>> needed to stop your endless, malicious harrassment.
does not go to the source of the statement, but rather to the source
of the comment of the statement. Apparently the mis-ascription of the

quote is more heinous than the quote itself. Truly a strange system of morality going on here.

If we were to take this seriously, then this is yet another workplace related confrontation that remains to be resolved through any other mechanism than the current denial and placing the blame outside of the two parties involved at work. Given the history of work related mis-haps that have been reported here (trashed files in a list server, mysterious emails, all stemming from an insider) it is not a mystery to even the most casual observer that parallels exist.

There is another answer that is more likely and benign. Its a joke! Lighten up! I am enjoying it. :-)

Has anyone received one notice from Fraudtenna? No. Why? Its a joke man! Albeit in poor taste, but consistent nonetheless. So let's defuse my opening comment about outrage. The quoted statement is obviously an invention for comic effect. This is also called irony or sardonic humor. I'm sure many here can appreciate the irony of claims of sincerity and noble effort coming from Fraudtenna. ;->

The list of pratfalls grows. The one I love is the unregistered Lottery held last autumn (wonder where the $1000 went?). I'm sure at least one legal counsel is blushing with the hope that it is forgotten. That joke was as old as three card monty or the shell game. Remember - just a joke. You can't get serious with someone who can't deliver a punchline or stumbles through the card switch - accept it for being a pathetic attempt which counts for nothing in the long run. Everyone should recognize it is not the quality of the comic content that counts so much as the delivery. Credit should be given for the attempt, and we can all enjoy the fumbles (something like that found in the English comedy Mr. Bean - or should that now be Mr. Boston Bean?).

Why doesn't this joke work any better? It was played out with DekeWhy. Re-runs seldom evoke belly laughs the second (third, fourth, fifth,... n'th) time 'round. At least that comic invention was somewhat original (Ah Deke, we barely knew ye!), but only once. To continue the English comedy metaphor, perhaps a more compelling character would be found in Black Adder's Baldrick. OK, so 90% of you were lost on this last reference - dry comedy is rare (and we don't have that much evidence of it here).

Hopefully, the comic line-up will improve in the new year. :-)

That depends on who defines "more efficient and effective", and how they define it. I can do Morse with just a simple rig/antenna and a key. No computer, TNC, or other stuff. Those other modes require extra equipment. Some of them require proprietary stuff. I carry a pretty good Morse encoder/decoder with me all the time.

And yes, they do abound. That's the trouble - there are too many of them. Digital tower of Babel. None of them are universal, like Morse.
>
>Telegraph. The word implies a written or drawn item sent or received
>over a long distance.

The word is a lot older than Morse. Before electrical telegraphs there were optical ones. The term is not meant to be taken literally.

> This is what Morse intended. He was seeking a
>system which recorded its output on paper.

He was trying to invent the teletype, but the technology of the time wasn't up to it.

> As I recall the story, his
>father-in-law was funding development of the telegraph and the man with
>the money persuaded Morse to go to market with what was already working,
>and not wait for perfection of the printed message development. It seems
>this was a case of father knows best.

Perhaps. He had people working for him who began to be able to understand the noises of the decoding machines directly. Eventually they sold him on the idea to get rid of the complexity, since a human was needed to work the machine anyway.

Radio used Morse from the very beginning. More than 100 years later, it's still going strong. Gotta love it.
>
>Telex and Teletype came later. There are many other digital data
>transmission codes and architectures. Most beat Morse efficiency by

>starting with code elements of equal lengths for the mark and space
>(zero and one) durations.

They require much more elaborate machines to encode and decode. And their "efficiency" is often a myth. Here's why:

The standard way of computing wpm is to see how many times a standard word can be transmitted in a minute. For plain language, the word "PARIS" is used.

In International Morse, the word "PARIS" (five letters and a wordspace) is exactly 50 time units long. In 5 level Baudot asynchronous RTTY, it's 42 time units long if equal length stop and start bits are used. In any code that's 8 bits/character or more, it takes even more time.

To do a fair comparison, the test to use is "wpm in a given bandwidth at a given S/N".

Morse uses "Hoffmann coding" - the most common characters are shorter. PSK31 uses Hoffmann coding too.

>Effectiveness is improved by error detection and correction along with
>automatic retransmission of garbled reception segments.

Sure - which takes even more time.

>Data
>transmission rates can be automatically adjusted to fit the condition of
>the transmission medium so as to optimize transmission efficiency.

Sure - IF both ends of the transmission are similarly equipped. Otherwise it's Tower time again.

Can you do ANY of the digital modes in complete darkness? Or while driving? Decent ops can do Morse under either condition.

>Trying to use Morse to compete with modern data transmission is
>equivalent to showing up at a gun fight with a knife.

Who is trying to compete? We do this for fun.

Your argument reminds me of powerboaters telling sailboaters to "get with it". Or people driving RVs making fun of backpackers.
>
>There was an American Cavalry General who advised his troops to dismount
>should their horse be shot from under them.

Why are all your analogies about fighting and death?

> Seems the coders have been
>beating a dead horse for years.

Not at all. We LIKE it. It's FUN. That's the idea. Do you yell insults out the car window at bicyclists and runners?

Despite decades of having "digital modes" pushed on the ham community, they make up only a small part of HF ham radio. Far less than Morse use. Why?

I cannot recall how many articles on digital modes I've read in QST - RTTY, packet, AMTOR, PACTOR, PACTOR 2, G-TOR, PSK31, Feld-Hell, and now MFSK16. To name just a few - there are lots more. When was the last time you saw an article pushing Morse as a mode? Yet it is more popular on the HF/MF ham bands than all of the digital modes put together.

Because we like it.

In article <3a4f89b5.8609511@news>, jflanders2@home.com (Jerry Flanders) writes:

>My 1963 ARRL Handbook is marked $3.50
>
>My 1968 ARRL Antenna book is marked $2.50

Here's a partial list of Handbook sizes and softback prices:

1948 - $2.00 - 614 pages text, 144 pages catalog (ads)

1955 - $3.00 - 619 pages text, 144 pages catalog (ads)

1957 - $3.50 - 627 pages text, 136 pages catalog (ads)

1962 - $3.50 - 640 pages text, 104 pages catalog (ads)

1964 - $3.50 - 640 pages text, 80 pages catalog (ads)

1967 - $4.00 - 648 pages text, 50 pages catalog (ads)

1969 - $4.00 - 656 pages text, 526 pages catalog (ads)

1971 - $4.50 - 642 pages text, 30 pages catalog (ads)

1976 - $6.00 - 678 pages text, no catalog

1978 - $8.50 - 678 pages text, no catalog

In 1979 the Handbook changed to the larger format, and enlarged. There was also a move toward hardcover.

A 1980 Handbook was $10 soft cover and $15.75 hard cover. By 1990 it was up to $23 hardcover only. The size increased to over 1000 pages in this era, and is now 1200 pages.

>When I first started buying QST at newsstands in about 1949, the
>Lifetime ARRL membership fee was a whopping $20 total. Somebody with
>some of these old issues could look back and see just when it started
>up - I think it was within a year or two of that.

You are mistaken.

Life Membership started in the late 1960s - 1969, as I recall. The price was fixed at 20 TIMES the annual membership, not $20.

Here's a quick view of membership prices (full membership, USA resident):

1950: $4

1960: $5

1970: $6.50

1980: $18

1990: $25

Note, however, that sometime in the 1980s the League began to offer discounts for multiple year renewals, senior citizens, and young people. For example, in 1990, one year was $25, two years was $47, and three years was $65. Senior citizens paid only $20 for one year, $37 for two years and $50 for three years. Licensed amateurs 13-17 who were the oldest hams in their households paid only $12.50 year. Those 12 and under who were the oldest hams in the house paid only $6.50!
>
>Just shows how we no longer have dollars - they are now dollarettes.

Look up what a typical wage was in those days. In the late sixties, a single $10,000/year annual income would support a family of four in solid middle-class comfort. For many back then, $10K/year would have been the lap of luxury. To live the same way today takes seven to ten times that much or more, depending on where you live.

<bamiller@texas.net> writes:

>Anybody recall what a Collins S-line sold for?
>
Hello Bob,

That depends on what type S-line and what era (they were made from 1959 until
the late 1970s).

Here are 1960 prices (all without shipping or tax):

75S1: $495
500 cycle mechanical filter for above: $50
32S1: $590
516F2 power supply for above: $105
312B-3 speaker: $27.50
312B-4 speaker/station console: $185
30S-1 amplifier: $1470

A typical "S-line" of a 75S1 with CW filter, 32S1 with 516F2 power supply and
312B-4 speaker/station console totals up to $1425. A lot of money back then -
and the prices went nowhere but up from these numbers.

But a round emblem 75S3B with the W2VCZ mods will outdo almost all modern
receivers in actual receiver performance. See

http://www.sherweng.com/table.html

for an interesting comparison.

Richard Clark wrote:
"The simplest method to achieve accuracy is to employ a transfer standard along with a technique that uses ratios."

I think that means we could have a 100-ohm resistor guaranteed under standard conditions to be 0.1% accurate and we could compare a 200-ohm resistor to the 100-ohm resistor by use of a 2:1 potential transformer. An impedance bridge operates directly between resistance ratios which are the same but may contain higher or lower resistance values in one side of the bridge, no transformer required. By comparison, we should get pretty good accuracy.

I remember working for a Ford dealer in the early 40`s and he had an assortment of Johansen sp? machined blocks of guaranteed accuracy. We used them to check the accuracy of our micrometers. Ford distributed those standard blocks.

Richard Clark also said something like, it is as important to make the right measurements as it is to make the measurements right. Makes sense to me!

Happy New Year.

You're the dead horse beater sir. I'm not about to launch off into any
diatribes on the subject beyond the obvious fact that you're just going to
have to learn to get comfortable with the fact that for a number of quite
valid reasons cw will continue to be heavily used on the ham bands well into
your OF days and probably beyond. Save your teeth, quit gnashing them over
the continued use of cw, you do your ham radio and we'll do ours and there
ain't a damned thing you can do about that.

The forward stagger works, of course, but space constraints limit me to
a 26 ft. boom. If I had room to swing a 48 ft boom, the design is trivial!
Surely if Force 12 can make the interlaced thingamabobs work, I can too!
Obviously my enthusiasm exceeds my antenna design knowledge (at this
point!). So I'll plod along with the hope that someone, somewhere has a
declassified AO-format file to share. I'd much rather tweak antennas on the
'puter and then build them, but if no one can help, I can always engage Dr.
Conehead in a meaningful series of usenet discussions.

Can you elaborate a bit more? I understand you propose a dipole
antenna and a scanner. However, I don't follow the "null off
the end" term. Does the dipole offer a directional indicator
which produces nulls (drop in scanner audio output ??) when
the offending pole is at a right angle to the dipole?
(Jeez, I hope this limb doesn't break)

Thanks

I have made and tested two of them. There are simpler ways to get the same gain in a given form factor. The reason they engender such a range of opinions is the fact that the "Dr." that "invented" them has no idea as to how to relate to the rest of humanity. He will tell you how wonderful he is, then if you disagree he will threaten to sue you. That's about the long and the short of it. For further entertainment, go to Deja and do a search for messages from Fractenna@aol.com

Do they work, in general, yes. Are they useful for ham applications? Who knows; there doesn't seem to be any definitive information. They seem to be a nitch application, like the quadrafiliar helix and other specialized antennas.

For some files on fractal antennas for ham use and comparisons thereof, see ftp://eznec.com/pub/MI2. I'm not sure if the demo version of eznec will handle these files, but it can be found at www.eznec.com if you don't have it.

There are other comparisons available on the net.

The controvery is not about fractal antennas, it is about the main proponent on this newsgroup. Many, including myself, consider him to be to be a mental case that will threaten to sue you if you post anything he disagrees with.

There is also a discussion group on www.egroups.com/group/fractalantenna that is moderated by the above mentioned person. Join if you wish, but don't expect answers to critical questions (my opinion).

Personally, I was really interested in the subject until the main propenent gave me a real blast of crap in response to a query on this newsgroup.

Oh yes, he has said he will not answer questions on this newsgroup; much the better in my opinion.

All the above, except for the links, is my personal opinion. You may find wonderfull things about fractals; if you do, please write an article for the ham world for the rest of us to see.

Every radio-related book published in at least the past 60
years will provide the information you need. There is still
a time and a place for such things.

If you're not prepared to splash out for something like the
ARRL Handbook (which answers your questions), please consult
a local public library. They usually have books on the
subject.

The supplied rubber-duck has 0db gain for a reason - the wide receiver
on the VX-5R will subject you to a lot of intermod with any kind of gain
antenna. If you don't live in a noisy RF environment (big city - lots
of pagers) try a tri-band MH-510. It's kind of long (20") but it's a
good antenna with some gain on 70cm.

I built up a quadature array of UHF Yagis and use a Radio Shack antenna
mounted preamp. It works fine on stations well over a 100 miles distant. It
was also the only thing readily available on short notice. There is about
230 feet of RG-6 between the amp and the TV set.

The whole thing is relatively close to my UHF/VHF ham antennas, but I've had
no trouble with them so far.

Yes, I too would prefer the Winegard, but the RS stuff has proven
sufficient.

I'd leave them dry as a little lubrication can pick up lots of dirt which
can do a lot of damage in a hurry.

Galvanized aircraft cable??
I've never seen aircraft cable that wasn't stainless steel.

Define what you mean when you say "Does XXXXX antenna work?"

Once upon a time, during a six-meter band opening in 1960, I connected the inner conductor of my coax to the screen on one window and the outer braid to the screen on the adjoining window and, within thirty minutes, I worked six states, Mexico, and Cuba on six meters. Would I recommend two window screens as a six meter antenna?

While I was stationed in Japan, I lived on a US military base where the base commander disliked amateur radio operators; we were prohibited from putting up antennas. I built an invisible dipole -- 65 feet of #26 wire, end-fed, 10 feet off the ground. I worked all Japanese prefectures and 30 countries on 40 CW using this antenna. Do I recommend that everyone use 75 feet of #26 wire, end fed, 10 feet off the ground?

Most anything that will conduct and that is some portion of a wavelength long will radiate. The question is not "Will XXX work as an antenna," rather, "What do I want to accomplish with my station and, in the entire pantheon of antennas, what does this for the most people?"

There must be a reason why most amateurs run dipoles and yagis. And the reason is not that most amateurs do not understand fractal antennas. If the fractal antenna did 10 percent of what it's maker claims, the dumpsters would be filled with yagis, tri-banders, quads, half-wave dipoles, and 135-foot-ladder-line-fed dipoles. Tradition is not all bad.

Jason- they work- but only as a small antenna is expected to work- not very well, compared to a real antenna.
There have been several made, according to reports I have seen. No big surprises.
the Controversy is NOT over the antenna, it is about the jerk who pushes them so hard, and is a constant (irritant/source of amusement) [select one] here on the NG. He is here, because he has been banned from several moderated lists. He can't be kicked off here, very easily.

Just read and enjoy- hope this helps

Yes; quite well. In fact, for example, there is no better small Yagi than the FQY described at

http://www.n1ir.com (up soon).

Its efficiency, gain, F/B, and 50 ohm match are unsurpassed by any other small Yagi design of similar size.

Two weeks ago, I came in second in the US on the 10M Contest (SSB SO LP according to 3830 'score rumors') using the 10M FQY.

In 2 1/2 years I have worked 295 countries on 10M with it, with very casual, and almost only weekend, operation.

I typically have EU QSO runs with rates of well over 200 Q/hr outside of contests and I feel like rare DX:-)

This antenna costs about 20-50 bucks to build, and is easily constructed.

In addition to the web site mentioned above (recently transferred from http://www.fractenna.com) some more detailed mechanical descriptions can be found in October 99 73 magazine, where KF7BS had the cover article with his 10M FQY.

There are several other ham magazines which have also published them. In fact, the only main one, worldwide, which has NOT published a fractal antenna article is QST/ARRL. I have declined their repeated invitations to assist, the latest being three weeks ago from WA1LOU (a nice guy put in a tough spot)

The best (and only) good web site to ask questions is:

fractalantenna-subscribe@egroups.com

I'm sorry I can't answer questions here due to the maicious nature of a few hams on this NG. There is no one else here who has experience with fractal antennas. You will find claims to the contrary but never any data or valid model results.

Happy hamming in the new millenium!

Hi Jason,

The remarkable feat of a fractal is the number of flavors it comes in.

Do they work? Yes.

As for the utility within or around an apartment, that is found in the small size and match offered. The benefits include nearly identical gain to the full size antenna, and a bandwidth that is broader than would be found in other small designs. In short, a better small antenna than examples of other small antennas.

How much better? Well for some examples of small antennas, quite good but not so much better as to beat the standard sized antenna and certainly no where near as good as a beam. That, unfortunately, is a strawman comparison. Browse the links I offer below to determine for yourself.

One controversy (for the antenna) is found in the braggin' rights that comes with one optimization over another. If you care to visit my page at:
http://www.qsl.net/kb7qhc/antenna/fractal/
you will find a survey of different designs where I show that comparing ANY fractal standing the same height as a standard quarter wave results in more signal towards the horizon. However, take this generality with a huge grain of salt and review my pages for the constant height models:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Height%20Comparisons.htm

Given that you are apartment confined, though, those pages may not interest. However if you browse
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Wire%20Comparisons.htm
you will find a table containing thumbnail size pictures of various fractal forms. Click on any, and you will be taken to a larger picture of the fractal form actually modeled (the thumbnail is first order iteration, the larger is second order iteration). Here you may observe the complexity of design (complexity of the physical layout that is) which many consider to be a major impediment (about the only true, technical, controversy). You will also be able to compare

iterations to observe how a fractal grows.

While you may not have personally written it, it is there for all to see that it is the viewpoint and opinion of the company (Fractenna). I do believe I saw on your oft noted web page that Phil was a "company spokesman" or some such thing. Since I have read on your site where Phil has the right to speak for the company and has done so to the press in the past, I can only assume that when he is using the screen name "Fractenna" that he is speaking for you and the company.

>Just out of curiosity, what was your hourly wage back then? How much did
>a house cost?

Well, here are some data points to consider....

Back about 1954, my uncle bought a nice 3 bedroom twin home in the town where B&W used to be for $12,000. He went into hock up to his ears to buy it, too - took every cent for a while, because it exceeded the "2 years gross salary" rule of the time. 20 year mortgage at 4%, which was considered almost usury then.

In 1979 I bought a very similar house four doors down for $47,000. I, too, went into hock up to my ears to buy it. 30 year mortgage at 10.5%, which was considered pretty good at the time.

Several years ago we both moved away. He went first and got about 8.5 times his purchase price. I got about twice my purchase price. His house was nicer ;-)

Compared to decent real estate, ham radio gear is dirt cheap.

>All the other modes are pretty old
>too. AM, SSB, SSTV, RTTY, all are fairly old and arguably lame also.

Good point!

AM - on the air by Fessenden as early as 1906. Hams were using it by 1920.

SSB - on the air for transatlantic telephone (AT&T) by 1923. Hams (W6DEI and others) using it by 1934.

SSTV - on the air by hams in the late 1950s (Cop Macdondald and others)

RTTY - on the air some time before WW2, used by hams as soon as machines became available (late 1940s)

The NEWEST of the group are 40+ years old. SSB is pushing 80 years old.

Nonsense. Do you think AO-40 doesn't support CW?

>There is nothing new to be learned about CW.

Sure there is. I learn something new about it with every use.

>If CW were a serious communications mode,
>commercial interests would not have abandoned it.

More nonsense. Utterly untrue. You rally are good at telling whoppers, Cecil.

Commericial interests have largely given up on CW because they can get more for
their money with other modes. Their bottom line is different than ours.

Just because something isn't done commercially doesn't mean its not serious.

> Any ham is free
>to learn Morse code and I encourage all hams to do so.

Same here. Why all the badmouthing of the mode?

> It is fun
>and may accidentally come in handy some day.

It's fun for many - but for it to be fun, it has to be learned.

>In fact, any citizen
>is free to learn Morse code. However, this is a free country and it
>should be a choice, not a federal regulation.

It IS a choice. Nobody is "forced" to learn it at all. What's left of the code
tests barely qualify as learning it at all.

And the regulation exists because of the ITU treaty.

Sorry, the demo version won't run calculations on these files. However, you can still open them with the demo version and view the antennas. You can also print the view, or view or print out a table of wire coordinates (Outputs/Show Description).

162. 10M ground plane question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-02 02:15:07 UTC
From: paul <paul@nospam.com>
Message-ID: <3A5139AB.7B9E@nospam.com>
Source record: 173234

Hello,

I want to make a homebrewed 10 meter ground plane antenna. I've got most everything together but have a question on the radials.

Is it possible to physically shorten the lengths of the radials by adding a loading coil to each one? I think that the radials (on a homebrewed antenna) would really be the only unattractive part as they would take up most of the roof. Any idea of what size to make the coil /whip combination? Any idea if this would improve, degrade, or be the same in terms of performance?

Thanks

Paul

Source record: 173235
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx

Jason,
The first antenna appears to be a shortened, loaded dipole.
Used with a tuner, and depending on the tuner used, It could
probably be loaded on bands 40 - 10 meters.
The second and third antennas, again depending on the tuner
used, probably could be used on 40 - 10 meters.
Would any of these three antennas work well? Depends on
what you call 'well'. Better than nothing, yes. Better than
anything approaching a 1/4 wave or 1/2 wave antenna, not even
in your dreams. It would be nice to 'discover' a very small
antenna for the lower HF bands, but these don't qualify.

165. TV yagi for 6M???

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-02 02:25:00 UTC
From: paul <paul@nospam.com>
Message-ID: <3A513BFB.37DE@nospam.com>
Source record: 173237

Hello,

I have a rather large Television antenna and I wonder if I could take the longest two rear elements and add a little length to them (or maybe a coil) and get them to resonate in the 50-54 Mhz band. I know that TV channel 2 is 60-66 Mhz (or something like that). I proved this resonance with an MFJ-259 analyzer. It is my theory that everything in front would act like some sort of director elements.

I would of course feed it with 75 ohm coax to the 300 ohm balun on the antenna. I know that baluns are lossy and wouldn't handle much more than a watt but it seems a simple, cheap way to have a QRP beam. We don't have a channel 2 in the area so I doubt if it would mess up my TV reception much (when used as a regular TV antenna).

Any thoughts would be greatly appreciated.

Thanks.

Paul

167. metal roof as ground plane

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-02 02:39:01 UTC
From: paul <paul@nospam.com>
Message-ID: <3A513F45.3F58@nospam.com>
Source record: 173239

Hello,

I am in the process of putting up a number of antennas on a metal roof. I see no need to use radials with such a perfect ground plane already provided. The roof is about 100 feet by 150 feet and we are working somewhere near the middle. It is a sloping roof 35 ft high on the one side and 20 ft on the other. We're fashioning brackets to make the elements vertical. I wonder if anyone has any ideas on what the roof's slope would do to the polar pattern of the antenna? Would it "steer" the pattern towards the lower side or have no consequence at all?

Thanks.

This is all very far away from the original thread.

The point(s) is/ (are):

1) the ARRL HANDBOOK's price does not represent the very cheapest it could be
and still turn a profit. I would guesstimate that price-point is of order $24
or so;
2) The ARRL HANDBOOK is designed to MAKE money to cover the extensive losses
incurred in operations at the League;
3) If the League didn't have the HANDBOOK then there would be a very severe cut
in many of the operations we have come to expect; I would speculate that things
which do not generate revenue and have low readership--such as contest results,
DXCC; and so on would suffer. And say goodbye to the percs such as the web
site; letters; bulletins; and so on.

What's the point(s)?

1) The League is a well run ship with no fat;
2) The League does have a cashcow--the HANDBOOK--that makes a lot of the other things possible;
3) Prices of items seldom reflect their costs. If you believe they do, then ask yourself how much money McDonald's makes on hamburgers (actually very little; of order a dime for a quarter pounder) compared to a coke (about 60-100+ cents per drink) and fries (about 20-30 cents per order).

So not everything scales as a KWM-2 ;-)

This MI2 file is a copyright file to me.

Roy Lewallen, D/B/A EZNEC, is illegally distributing and publishing this file. Hams and others are warned that downloading said MI2 file is a further violation of federal copyright laws.

Mr. Lewallen will be served shortly with a cease and desist order. If he fails to stop this illegal distribution and publication of this copyright file, he will be sued and criminal charges will be brought against Lewallen D/B/A EZNEC. If Mr. Lewallen does not remove the file immediately then litigation will also seek to determine who has sought to download this file illegally, through Lewallen's distribution and publication on the site www.eznec.com.

Would degrade compared to full 1/4 wl radials. If you hate radials, make
a 1/2 wave vertical. It will work ok without radials. The number of
turns would depend where on the radial you placed the coil. The farther
out, the more turns needed, and also more loss in general. But you do
get better current distribution. 1/2 to 3/4 the way out about the best
place overall. You could use regs vertload to get a good idea of the
coil needed for such a setup. Just pretend the radial is any other
loaded 1/4 wl vertical. All the normal methods apply. MK

knowledge concerning CW.

> Commericial interests have largely given up on CW because they can get more for
> their money with other modes.

My point exactly.

> Just because something isn't done commercially doesn't mean its not serious.

Commercial = functional = serious, amateur = hobby = fun.

> Why all the badmouthing of the mode?

I have never badmouthed the mode. I have badmouthed the regulation that
forces a single mode down the throat of every HF amateur radio operator.

182. Alliance HD-73 Rotor - Need Info

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-02 05:12:31 UTC
From: JSPS <jsps999@earthlink.net>
Message-ID: <c1o25t827sms740uqsnl6r7m6coaausduu@4ax.com>
Source record: 173251

I hope this is not off topic for this NG, I appologize if it is.

From an estate sale I recently acquired an Alliance HD-73 rotor &
control box.
I knew that these were in good working order and were in use until
the elderly Ham passed away recently.
Unfortunately, the persons(s) who took down the tower, etc
misplaced/lost the rotor control cable with it's what I believe to be,
but not entirely sure of, a **customized** 6-pin plug at the rotor end
of it.

I need to know this info:
To corrolate the control box's numbered terminal strip with
the color code of the length of 6-wire control cable "tail"
going into the HD-73 rotor housing.

Thanks in advance for any info.

Note the tortuous wording that makes it look like a big deal, but is
really as clear as mud. Apparently, if I did down load it, I am OK, only
if I only sought to, is he after me. Further, since the file in question
is NOT Frackies, then any download would not be illegal, so another
qualifier bites the dust.
I am having a hard time seeing just what he is after, since all the
things that bother him are not pertinent to the action he proposes.

For what it's worth- I have the file, I did not download it from the
EZNEC site, and I hope he comes for me- I am on a retirement income, and
could sure use the proceeds of my countersuit.

Hope this helps- Bill

Hi, and happy new year to the group -

I am considering putting up a wire antenna for casual
HF use (100W class). I would like to operate on as
many HF bands as possible. Available supports are
a 40 foot tree on one end, and an 8 foot fence post
on the other end; so this thing would be something
of a sloper. Can feed approximately in the middle,
with either ladder line or coax. I have a new antenna
tuner available (MFJ).

Any opinions out there as to whether a multiband dipole,
a windom, a G5RV, a random longwire, or ??? would
be best suited to this situation?

...Thanks, Old Ed

I live in a no antenna development. Because I have cathedral ceilings I have little space to put an attic antenna except in my garage, which is only about 22' long. I have put up 2 sets of Hamsticks (dipole configuration) in the garage attic, one for 40 and one for 20. They work well for my type of operation which is CW ragchewing only. I have yet to lose a contact in the 3 months I have been using them, and many chats have lasted well over an hour. I get about the same reports as I do when I use the Hamsticks CW mobile, which I guess is logical, generally 559 to 599. I was surprised that I have few RFI problems considering that the Hamsticks are within a few feet of power, cable TV, and phone lines. All my TVs except the one in the shack are completely clear. The phones have some very minor clicks when I key and are useable, and the only real problem was a GFI socket that kept tripping off and darkening my outside decorative plant lights. That was easy to fix, I just replaced it with the old fashioned kind. I'm hoping that the neighbors are as lucky as I am with my RFI, but I ain't asking... :-)

Anyway, I have digressed. To answer your question about portable operation, yes, Hamsticks should work just fine...

Paul,
The 'tilt' will have some affect, but probably it will
be very slight. I don't think I would worry too much about
it. Another point to think on is that if you use the roof
for a groundplane, you're affectively making the roof of your
building part of the antenna. Any wiring, etc, are going to
be in very near your antenna and will be subject to RFI. (I'd
have to try it too, though.)

Source record: 173122

Hi Paul,

There are lots of instances where hams have used TV antennas for 6m. One guy here in Massachusetts has an old Radio Shack 13 element vhf tv antenna that he uses on both 6m and 2m. It works so well for him that a couple of other guys went out looking for that particular model from Radio Shack, but found that it was discontinued (figures, eh?). I've also used a "bat-wing" style tv antenna for both 6m and 2m with some slight directivity.

The baluns used on tv antennas can be used to tx low power, and work just fine. I don't know what pwr level they might break down at, but I know that the one being used on the Radio Shack antenna has been fed up to 30 watts carrier on AM on both 6m and 2m, and he's still having no problems with it.

It's a shame that your antenna doesn't show resonance down to 50mHz, though, as that would certainly make it a nice plug'n'play dual duty antenna. Since these are usually a log periodic dipole array design, it would probably be better to try to add elements onto the back end of the antenna, rather than making the last two elements longer, since that would disrupt the log periodic design. In other words, if you add length to the elements, they also need to be moved further back to maintain directivity.

At a guess, I'd say that the performance hit would be less if you simply loaded the antenna up on a tuner, rather than lengthening the last two elements.

This MI2 file is a copyright file to me.

Roy Lewallen, D/B/A EZNEC, is illegally distributing and publishing this file. Hams and others are warned that downloading said MI2 file is a further violation of federal copyright laws.

Mr. Lewallen will be served shortly with a cease and desist order. If he fails to stop this illegal distribution and publication of this copyright file, he will be sued and criminal charges will be brought against Lewallen D/B/A EZNEC. If Mr. Lewallen does not remove the file immediately then litigation will also seek to determine who has sought to download this file illegally, through Lewallen's distribution and publication on the site www.eznec.com.

Nathan Cohen, Ph.D.

>IMHO, the value is diminished --as a general EE ref--compared to other pubs, >especially CD-ready ones.

The Handbook is available on CD-ROM. Has been for several years.

It was never meant to be an EE level book. It's a practical radio book. EE is a lot more than radio.

> Example? ART OF ELECTRONICS by Horowitz and Hill.

Which costs how much and is revised how often?
>
>In 1962, I am of the opinion the handbook was the primo resource.

For hams, yes. For EEs, no. Same as today.

EE level references then were books like the Radiotron Designer's Handbook and the IEEE "Reference Data for Electronic Engineers".

>I bought my
>first one in 1967 for $5.00.

If you lived in the USA then, you paid too much. It was $4 in 1967. That's when I got my second one.

> Had all the tube configs in it:-)

No, it didn't.

It had a sampling of tubes commonly used by hams. Also some transistor data. Lots of practical construction projects.
>
>Glow lil' glowbug!
>
Big ones too.

The whole point of the Handbook is to fill the gap left by other publications. It's not meant to be an EE level text.

No, it's not. The existence of cw and the cw regs have no effect. The license test requirements may, though.

> My ex-boss is a tech in Colorado. I'm in Texas.

How many miles is that?

>We can't legally talk to each other until he satisfies the code regs.

Not true.

There's amateur satellites. Tropo scatter. Ducting. Other forms of VHF/UHF propagation.

To use the HF/MF amateur bands, he needs to upgrade. That takes a 35 question written test and a simple 5 wpm code test. And a VE fee.

>for
>> their money with other modes.
>
>My point exactly.

Money isn't everything. Commerical use is not the yardstick to measure amateur
pursuits. Sailboats have almost no commercial application.
>
>> Just because something isn't done commercially doesn't mean its not
>serious.
>
>Commercial = functional = serious, amateur = hobby = fun.

That's completely incorrect and illogical.

Things which are "functional" and "serious" are not limited to commercial use.
Activities from disaster relief to election officiating are done by volunteers,
who are not "commercial" in any sense of the word. But they are sure "serious"
and "functional".

A thing can be "commericial" and "fun" at the same time.
>
>> Why all the badmouthing of the mode?

When discussing antennas, 'small' means small in comparison with the wavelength they will be used at. An antenna which has its longest dimension less than say 1/8th wavelength can be considered small.

Radiation resistance of most antennas increases in proportion to Square(Length/Wavelength) where Length is usually the longest dimension. Sometimes it may increase according to the 4th power of Length/Wavelength depending on an antenna's geometry.

But the most important characteristic of small antennas of any sort is power radiating efficiency. They all have poor directivity gain.

Efficiency = (Power in)/(Power out).

Radiation resistance, Rr, is only half the story. Its actual value doesn't matter. It varies greatly from one antenna to another.

The other half of the story is Loss resistance RL. This consists of conductor resistance + ground loss resistance. Again its actual value doesn't matter. It varies greatly from one antenna to another.

What REALLY matters is the RATIO of one to the other because -

Efficiency is given very simply by -

Rr/(Rr+RL) * 100 percent.

The Magloop is the most efficient amongst small antennas. Its radiation resistance is very small, perhaps only milli-ohms, but by using a copper tube 1 to 3 inches in diameter the conductor loss resistance can also be made very small. By mounting it a few feet above ground and away from other structures the induced ground loss can be made negligible.

A Magloop can have a useable efficiency even when its diameter is only 1 percent of a wavelength. Download program MAGLOOP4 from website below and obtain some performance figures.

But to be correct, do you think the height above ground
should be included as one of a magloop's dimensions ? The
feedline has to be at least as long as height.

>
>No, it didn't.
>

I am sure it did not have the pin configuration for my DeForest Audion 427; in the context of the discussion, the statement is correct--it had all the USEFUL and NEEDED tube configs.

No doubt more obscure/special purpose tubes were found elsewhere. The point is that you don't find that stuff in the HANDBOOK anymore.

>It had a sampling of tubes commonly used by hams.

A large one; and not just used by hams.

Also some transistor data.

Hmmm... how much in 1967? I don't remember.

Nor did I say it was. You would be hard pressed to find caluclus in its 1967 pages.

What color was the pre-1967 cover Jim? Just curious. Also, no color as I recall.

I don't think that was Harrison's intended context, I think he's bitching about the cw setaside bandwidths. As far as the squawks about the weenie 5wpm code test is concerned I don't like it and I'll continue to oppose dropping it but nobody is gonna die if it happens. Where I'll really get torqued is when they start bawling about letting phone move down into the low ends of the bands and clobber cw and the digital modes. Expanding the space for a 67 year old mode at the expense of a 100 year old mode? There's a huge chunk of "technological progress".

Surprisingly, Radio Shack is not completely out of the picture.
They have (or had) an in-line 75 ohm preamp that works in the
UHF and Small Dish Satellite frequencies. It uses an MMC that
has a less than 4db (I think less than 3db) noise figure
at UHF. I've used one, and it's actually quite good. You may
need to look carefully for it, because it may be under the satellite
dish accessories (it's also used to extend the cable length to
DBS dishes) rather than under 'regular TV' accessories. I'll try
to remember to look for the part number this evening.

I hope that proves to be the case but it's obvious as hell that "certain
others" are quite anxious to hasten the elimination of Morse via means other
than just attrition. They're too lame to run cw, they don't like cw, whatever,
"kill it so that I can have more space for MY mode". Among less obvious reasons
they have for trying to put a hurt on cw. Watch it start.

Finally: We agree. But my protest was that Rich -maybe without meaning to- seemed to criticise CW as a useful communications mode just because it has been around a long time and other more efficient modes exist. I totally disagree with that. If he doesn't want to use that's his business.

Back to antennas. Freakie's disruptions here are more than enough.

This is OK, but there is more to it.

Electronics, as it pertains to Amateur Radio, is no longer the semi-intuitive "gut feel" type of technology that it used to be. It has become very clear that this approach is not working very well any more. Like it or not, the kind of simplistic explanations that used to be OK when radio was, at least on the surface, a lot easier to grab hold of, are just not good enough any more.

To be more explicit, radio technology has never been all that simple. Look at the very early Proceedings of IRE and you will see some science that most radio amateurs were, and still are, completely unaware of. Nevertheless, amateurs could understand basic principles and practice well enough to get on the air with home made gear.

No longer true, except *maybe* at the most elementary levels. Even the QRP rigs are carefully thought out examples of solid state "system design".

If you look through the ARRL Handbook you will see thousands of interesting items that previous generations could not even imagine (I have a 1938 edition). And a basic fact is that these matters can no longer be understood or appreciated on a *purely* intuitive level. The world has changed into a place where math and science skills are basic ingredients, not merely icing on the cake or some kind of ego trip for academic types. The ARRL Handbook these days recognizes this, and tries to get a balance between science and practice that is optimum for radio amateurs and students, but also challenges the mind in new directions.

Like it or not, if we want to be knowledgeable, even at an introductory level, we have to get tuned in to these new ways of thinking about amateur radio technology.

In other words, the word "practical" doesn't mean quite the same thing any more. And one of my favorite "speeches" is that with the personal computer and software for math and design and analysis, it is easier than ever and getting easier all the time to be a lot more scientific about how we deal with the "practical" matters that pertain to amateur radio.

And if we are going to move beyond the mythology and folklore and snake-oil that has pervaded amateur radio for many decades, we have get up to date in our skills and attitudes.

Hi to all,
I have come up with a possible problem with my dear neighbour as my X-7 beam will unfortunatly be abt 4 feet over our border fence. I am looking at a few possibilities before I may have to go to more expense and move the tower. The main possibility is : what would be the effect of shortening the longer elements ?

Any replies greatly appreciated

Mr. Hsu:

You innocently (I assume) posted your query relative to the performance of "fractal" antennas on 01/01/01. Note that in no time at all the answers to your question drifted substantially away from answering your question. Maybe that says something about the antenna.

135 feet of wire fed in the center with ladder line. You will need an antenna tuner at the rig end. This is a simple, effective antenna that will load on every band, radiate well, and is quite forgiving. You can purchase one already assembled from any number of suppliers. A place called Radio Works has a neat device called the Ladder Lock that serves as a center insulator and support -- I use that on mine and it prevents wire twisting and breaking at the center.

Jim, NE2EY wrote:
"The existence of cw and cw regs have no effect. The license test requirements may, though."

Bingo! You`ve hit the nail right on the thumb! Keeping otherwise competent "wannabes" off the bands kills amateur radio for no good reason. Technical developments have presented other pursuits of greater ease and attraction to drain the pool of wannabes. If amateur radio is to survive, it must be easy and attractive, too.

You don`t pass a horsemanship test to get an automobile driver`s license. Neither must you pass a test on the design and construction of automobiles. Technology has made such tests no longer needed. The same is true of CW and thorough technical tests for issuance of an amateur radio license. There is no need for exclusion of fine people because they don`t like code or the technical side of radio. If they are competent people without a record of malfeasance, and pass a minimal test on rules and operating requirements, they should be issued an unresrricted license to full amateur priveleges in all bands, just like drivers are licensed. The applicants already are owners of the airways just as driver applicants are already owners of the roadways.

The idea that a code or technical test is going to keep miscreants off the air is illogical. The character mix of licensed amateurs is certainly no better than most random groups. There are saints and sinners among coders and nocoders and among techies and the clueless in almost the same proportions.

The problem is vanity. Some amateurs prize an amateur license as some sort of credential of superiority. If everyone could easily get a license, the credential would lose value. Exclusivity is needed to give class to the club. I pity them.

Best regards, Richard Harrison, KB5WZI

>
> Yes, it does.

OK, Jim, you're on. From Webster's: "potential - possible, as opposed to actual." Please tell us what is possible with CW and A0-40 that has never before been accomplished in actual practice. CW over a satellite was a potential at one time. It's not anymore. It has already been done. It was a potential in the 50s. I suspect it was actually accomplished in the 60s.

> >CW is a 100% mature communications mode.
>
> If so, that's a good thing.

If CW is a 100% mature communications mode, then it has exhausted its potential. You cannot have it both ways.

> That body of knowledge expands every day. You glimpse but a small part of it.

OK, Jim, you're on. Please tell us something new that has recently been discovered about the CW mode. Better yet, speculate on something new that will be discovered about the CW mode.

> >Commercial = functional = serious, amateur = hobby = fun.
>
> That's completely incorrect and illogical.

Of course, it's true in general. Ham radio is *usually* used as a *hobby* for *fun*. Don't tell me that the majority of ham QSOs are serious (although prostate problems can be serious :-). I was born at night but it wasn't last night.

> >I have never badmouthed the mode.
>
> You badmouth it at every opportunity.

Telling the objective truth about a mode is simply being honest about its capabilities. That's not badmouthing. CW for serious communications has gone the way of the horse for serious transportation. Both occupy small niches compared to their heydays. As far as I can ascertain, CW used by hams on the HF ham bands has never saved a life. Is that badmouthing or just an honest

statement?

You are like my Mother. When I tell the objective truth about the Bible,
she says I'm badmouthing it.

> > I have badmouthed the regulation that
> >forces a single mode down the throat of every HF amateur radio operator.
>
> No such regulation exists. No single mode is "forced" down anyone's throat.

Of course it is, Jim, because of the ITU treaty. When OOK Morse is treated
equally to the other modes then it will have ceased to be forced on anyone.
That won't happen as long as an HF ham is not free to choose his first mode.

I have a 450 window line fed 160 meter dipole and need to shorten it to get the ends farther away from metal supports. I was thinking of putting in a set of Unadilla 80 meter traps which would result in shortening the overall antenna length by about 40 feet or so. Would I realize a substantial loss in performance on the higher bands? I use the dipole for primarily 160 and 80 meters.

> seek to determine who has sought to download this file illegally, through
> Lewallen's distribution and publication on the site www.eznec.com.

Perry Mason says "good luck in the contest". Being as most counters only
show the main ISP addess and not the individual address, I don't see how
this will be possible. If you "Heckle" went to my web site, I don't see
frektenna at aol.com, I would see something like:

Dec 24 17:38:33 spider-wm033.proxy.aol.com Win 95 MSIE 5.x

So you can see any hopes of nailing the "perps" in this case will be
futile at best. Also when I was talking to Perry on the phone, Paul
Drake broke in on the other line. He was very angry, and said for me to
tell you to quit calling him at all hours of the day and night. He told
me in no certain terms that he does not want to be your new boy toy.
Hope this helps... MK

Is your DeForest Audion 427 a triode with a 5 pin base? If so, the base layout
is in the 1967 version.
>
>No doubt more obscure/special purpose tubes were found elsewhere.

The tube data in the Handbook was not meant to be complete. Many common tubes
useful to hams were not in there. And the data was limited - no characteristic
curves at all. Doesn't mean it wasn't useful, just that it was limited. Anybody
doing real design work would get a tube manual.

>The point
>is
>that you don't find that stuff in the HANDBOOK anymore.

There are still a few tubes listed in the 1988 edition - I don't know about the
2001 version. Tubes are no longer electro-politically correct, doncha know?
>
> Also some transistor data.

>pages.

That's the point - it was to present radio with a minimum need for background in math and science. Most of the projects were not and are not "state of the art" in any sense, but most can be built and made to work without lots of tools and test gear. Perhaps that's what is most missing today.
>
>What color was the pre-1967 cover Jim? Just curious. Also, no color as I
>recall.

The 1967 cover was red. The cover color changed every year. I have several of them from 1948 onward, in various stages of decay. All of them have been useful to me as a radio amateur, but their usefulness to me as an EE is rather limited. But they were largely responsible for getting me started on the path to engineering school, and for that I am forever in the debt of the League and the authors of the Handbook.

What is missing from the ARRL library today is a sequel to the '60s masterpiece "Understanding Amateur Radio". This book, a sort of "junior handbook", taught the basics well to a non-engineering audience and had lots of practical projects. Cost was about half that of a Handbook.

I made both of those eggbeaters also. Used #6 wire for reflectors and loops on the 2 meter, and #6 for reflectors and #8 for loops on 432. The wire is cheap and uninsulated, at your local electrical supplier or home center. Also used clamp type terminals for this size wire to make adjustment of length easy. Have worked 3 birds on close passes, using these antennas and 10 watts!

Thanks to Jerry for the article!

Anything that is obtained with little effort is something regarded as something of little value.

When one had to travel to the FCC office and take an exam and wait a month or more to find out if you even passed the test created a sense of value that caused you to be really careful in the way you operated for fear you would loose that privilege you had worked so hard for. Today with instant results and call signs issued within 48 hours, no code, and very little effort the license is only slightly harder than getting on CB. We then complain that the FCC isn't doing it's enforcement job. We used to take pride in policing ourselves, however today's "I can do my own thing" attitude makes that impossible. There is no peer pressure, judgement of another's behavior is considered gauche and we lament the conditions of the bands.

We need less quantity and more quality in amateur operators.

Hi Richard,

I have also calibrated Gauge Blocks (Johansen sp? machined blocks of guaranteed accuracy) to the nearest 100 nano-inches by this method.

This was a fascinating experience where the test apparatus sitting on the measured block would peg the indicator meter as I approached the test bench. The IR emission of my body was absorbed by the block which in turn would expand enough to confound the measurement (about one micro-inch). I had to arrange my test components by nudging them around with a yard stick (didn't want my body heat to soak them) and standing back at lest ten feet to wait for the meter to settle down (cool off). Not very productive work actually, with these long cycle times. These blocks became the transfer standards for the utility blocks that Richard describes above, which in turn became the standards for the calipers. This lineage is known as traceability when the most accurate component is calibrated by NIST.

Bridges are the absolute best approach to any measurement requiring accuracy and they have been with us for more than a century working robustly. There are many factors to consider in their use, but such factors are comprehensible and obvious once revealed. They also allow measurements of vast resolution, at least 6 places for some gear. I have worked with many, many bridges. Most fall into the category of the Wheatstone Bridge (which few people have actually used, but think they have), but my favorite is the Kelvin-Varley divider. One bridge, the Hybrid Bridge, is another favorite of mine for confounding experts in "matching and loading." Another such brain twister is the "Magic T." All of these are very simple circuits.

Does anyone know any good web sites that show how to install small yagis in trees??
The reason I'm asking is because I'm thinking of getting on the air but I live in an area with a lot of tall trees, and why spend the money for a 50 ft mast when you already have one (that you dont have to go to radio shack to buy) in your backyard!

Thanks

984/f is one wavelength in free space. Multiply that by the velocity factor of the coax, e.g. 0.66 for RG-213. 135 deg is 135/360 of a wavelength.

Let's say it is for 40m. 984/7.15=137.6' 137.6x0.66=90.8' (135/360)x90.8=34.06' Fine tuning may be necessary to get the pattern you want on any certain frequency.

From what I have gleaned here at HQ, that is correct. Most hams who buy the Handbook seem to buy a new one every few years. Before I came to HQ, it was about 4-5 years apart for me.

> >Ye..ees...and many also had the HANDBOOK.

I have given away copies of the Handbook to non-ham engineering contacts I have in industry. Their look of appreciation (in both senses of the word) appeared to me to be sincere. I would bet a lobster dinner that they didn't throw it away when they got it home. :-)

Hi Fred,

It seems this discussion is bordering on the tense side - let me add
some more. :-)

Your comment on the appearance of worth is right on, but I would say
that it leads to an incorrect conclusion. We need more folks on the
air not less (this is the political base building that we need to
pursue to insure the future). The obvious solution to their
participation is to ADD SPECTRUM. Only a large constituency can make
that a possibility - not the shrinking one we have at the moment.

As for CW operators having restricted frequencies, sure, with more
spectrum no problemo. We should even bring back Spark Gap technology
(myself I would love to start up an amateur radar station). Why not?
(I'm sure some overstuffed soul will point out why not.)

I`ve waited until now to advertise my ignorance on this topic. Delay in degrees by the unit length of coax has always seemed to work for me. But, several months ago I gave a similar response to yours to what I think was about the same question. Roy was prompted to say such simple phasing works for 1/4-wave and 1/2-wave sections only, if I understood his response. Actually, I still don`t know what he was talking about.

Source record: 173177

More than "fine tuning" will be required.

Unfortunately, the method Cecil cites doesn't lead to a 135 degree phasing network. Here's why: The phase delay (of either current or voltage) in a transmission line equals the electrical length (Cecil's calculation) only if the line is terminated in its characteristic impedance (or in a couple of special cases with special lengths). If you start with two elements which have exactly, say, 50 + j0 ohms impedance, then feed them with equal magnitude currents which are 135 degrees out of phase, you'll have feedpoint impedances which are very different. Neither will be 50 ohms and both will be reactive, and they'll be different from each other. Not only will the delay through 135 electrical degrees of line not equal 135 degrees, but the magnitude of the current will be transformed. I'm not talking about a small effect, either. It's easy to get an error of 30 degrees or more, and magnitude transformations on the order of 2:1. The result is that you don't get anything like the pattern you planned. This is discussed in detail in Chapter 8 of the _ARRL Antenna Book_. There's no network there for a 135 degree feed system, but I recommend reading it so you understand the problem. (Cecil, it might be good for you to review it too.) A series of articles describing phasing networks applicable to any phase angles was written by Forrest Gehrke, K2BT, years ago in _Ham Radio_. You'll find the reference at the end of Chapter 8. A general method is also described in _Vertical Antenna Handbook_ by Paul Lee, N6PL, published by CQ. This is the method used by broadcasters and, although complex, will work for any phase angles. It is possible to feed two elements correctly using only transmission lines, if you know how to calculate their lengths. You'll find this method in "The Simplest Phased Array Feed System -- That Works", in the _ARRL Antenna Compendium_, Vol. 2. It can be applied to a 135 degree fed antenna.

Finally, you might like to download fdsp~.exe from ftp://eznec.com/pub. It's a self extracting ZIP file describing the "Field Day Special" antenna, which is made of two elements, spaced 45 degrees and fed at 135 degrees. It resembles a ZL special, but can be made with equal element lengths so you can easily remotely reverse the pattern. A simple program is included which allows you to fiddle the element and phasing line lengths to get the desired results, which include a very good F/B ratio. Often you can find a combination that doesn't even require any external impedance matching.

I fear the shortening the longer elements will deteriorates all the
performance of the antenna.
With my X7 I had some problem with SWR pattern on 20mt, becouse of the
hight above the roof, and i wrote to CushCraft. They said me that
it's possible to change the dimension of the elements for a few
centimeters only.
GL for your problem and enjoy X7.

It is remarkable how a little dedication was able to overcome the
limitations of available instruments and produce such wonderful long
standing results. It is a testimonila to them as much as anything. However
in order to keep these subject really alive it would be nice for some
contemporary workers to repeat the work if only to engender the sense of
wonder once more into a living person.
Who knows what might have been missed first time around due to the
limitations of the equipment, the poor reliability or repeatabilty of the
equipment and of course the limited state of knowledge at the early time of
the original experiment.

I don't know if any watched the program Longitude on BBC 2 which was a
re-enactment of Harrison's trial and tribulations and the sheer pig
headedness to proceed with limited resource gradually building up his
knowledge to the point where by pure persistance he reached his goal. Those
early self taught men had some luck at being the first at the problem, it is
difficult now to find challanging opportunities in the physical sciences
that can be undertaken by an individual. Imagine the sheer discipline of
Joule toi carry out the volume of experiments neccassary to produce the
results that he achieved. And all this from a simple brewer, not a man of
scientific training or vast independent means.

Don't forget the admirable work of Wheatstone
Application of the Kirchoff's Laws to the Wheatstone Net

Hadley describes an experiment and demonstrates the associoated Mathematics,
however there is no mention of error analysis. This is a later statistical
technique. What my original suggestion was intenede to awaken was a a
consideration of early measurements in the new light of more recent
learning.
The Metre Bridge is described, and the Post Office Box gets a mention, but
the means of indication the balance of the bridge is a mirror galvanometer.
Exciting stuff, with rudimentary equipment draging the truth from a
reluctant mother Nature by the sheer effort and application of dedicated
man.

This is the spirit that was early ham radio, the mere fact that nobody else
had done whatever it was that the experimenter was attempting, the
excitement of being the first to pass that way. Perhaps in repeating the
experiments some of that wonder can be recaptured NOW.

Yes indeed, modern conveinience has made us quite sloppy, the rigour of an earlier age seems to be missing from much of what we do today. Not only in this feild but some of the best Literature was pened before WWII, after that time the attention to detail seems to have suffered.

Indeed I devised a very acurate method for calibrating signal level, it awaits a good high temperature noise standard that is easily reproducable in the confines of the typical Ham workshop for it to be applied generally to the hobby. All of that contest data could be put to some reall use in producing good dynamic maps of the propogation conditions around the world.

Hi Gary,

I have been guilty (once again) of painting with too broad a brush in
regards to ingenuity missing from our age. Your posting helped me to
recover from that by adding some accomplishments that I regard as
quite remarkable.

The Standard Cell, once the cornerstone of the Volt, has gone the way
of the Dodo. When I see the retired standards in the rummage boxes at
Ham fairs, it is somewhat saddening to observe the former champion now
languishing in the metaphorical gutter. These units had been in
service since the turn of the century (100 years ago - not last week).
They represented the peak of electro-chemistry with an accuracy
bordering on 10's of microvolts (depending on length of service).
Those who find one at a rummage sale would be advised to orient them
upright (so that they appear to you as the letter H) and allow them to
settle for a couple of months. There are MANY instruments in the
rummage market that were tailored for the standard potential of 1.3
odd volts. If you thought finding rare matched FETs was difficult,
these will become even rarer (but could be replaced with standard
Zeners).

The Josephson junction is the new (relatively speaking) and current
champ of the Volt (unless they've aced me with something better).
This standard of the Volt is based on Quantum mechanics and pulls that
formerly ethereal math into the work-a-day world.

Another stroke of genius is found in the standard capacitor that is
co-axial in design and using laser interferometry to measure the
plunge of the piston into the cylinder to provide a very accurate
delta C. It is instructive that the technique is what provides the

boon in accuracy, and not the component nor the laser (both necessary, but alone would not suffice without that AHA! of the delta).

Moxon says you don't have to put a loading coil in each one. What
you do is tie the three or four radials together, make them insulated
from ground, and put a single loading coil between the shield and radials.

This way the exact length is unimportant, but efficiency will decrease the
more
you shorten them. You adjust the loading coil to tune the antenna. You
probably
won't get the lowest SWR this way, but don't worry about that too much.

Denis- this may sound like a strange way to fix it, but, depending on the tower (Rohn - ?) you might have the least trouble and expense by having a four-foot stand-off made to mount the rotor and mast off to the side, away from the neighbor. Rohn has some in their catalog, but I think the ones for 25g are only about three feet. I have one that is sturdy, but only three feet offset, with a 34 inch long tube (vertical)

Good Luck- Bill-W4BSG

On Mon, 01 Jan 2001 21:25:00 -0500, paul scribbled:
>
>I have a rather large Television antenna and I wonder if I could take
>the longest two rear elements and add a little length to them (or maybe

A local 'business' man threw up a LPTV Pay TV station on channel 2
back in the 80's. It did not last very long -- but he insisted on
having his customers install cut-for-channel-2 TV antennas. They
grace the roofs of many homes in town -- even tho' the TV-2
station is defunct, cable has come and peaked, and many folks are
now on to satellite TV.

Anyway.... I've been able to get a few of these for free -- just
for the taking of'em down. They are 5-el on a 60" boom. Most
of the elements are there for marketing -- versus practical gain.

I use one for portable operation on 6M. It works fairly nice.
What I did was figure the % delta between the middle of the
channel 2 and 50.200 mcs. Then I pried open the flattened ends
of the parasitic elements and shoved tight hairpins of calculated
length, 10 gauge aluminium into the end and staked them in place
with a 1/8" pin driver.
For the driven element -- which was a folded dipole -- I used the
same 10 gauge al. wire to fashion big open hairpins to extend the
size of the dipole -- *leaving* the original folded dipole alone.
Thus, I had a new-sized dipole with the ends of the original acting
as a short across the new sized 'fold'. This seems to have
(serendipitously) given me a near-50-ohm feedpoint.
I did not putz around with re-positioning the elements on the boom.
As an added 'bonus', it folds up -- as it was folded coming from the
factory -- and makes transporting it fairly easy.

All of it Standard Amateur Radio Practice.

It works.
I use it.

It would be a good choice for someone living where ham antennas
are 'discouraged'. You look'em straight in the eye and say:
"It's a TV antenna!" -- and show them the sales receipt and
installation instructions.

I'd hesitate, tho', to use an "All Channel" TV antenna. Any
harmonic or spurious emissions from your rig will *also* be
happily (and 'gain'-fully) radiated by such an antenna.
A 'tuned' antenna does give some rejection in such a case.

Great, Cecil.

Do you think he would still be doing so if you had used the expression,
"learn the piddling 5-wpm code?" I hope that the expression hasn't been
used on too-many would-be hams. I would strongly discourage its use.
Perhaps it would be more effective to point out that learning code to 5 wpm
isn't very difficult; generally a few days practice after memorizing it
works for most people. Somehow, it sounds a bit more encouraging that
"learn the piddling code."

The main reason I took the effort to write the material in the ARRL Antenna Book was so I wouldn't have to keep answering the same question over and over. If you haven't looked at it and really want to understand, I suggest that you do read it. A few newsgroup postings aren't adequate to convey what took a whole chapter to explain. If you've read it and still don't understand, then I've failed as a writer to communicate.

I will, though, give an illustration of what's going on. People with EZNEC or the EZNEC demo program can follow along. (Feel free to change the Units if you prefer to work in feet and inches.) This could all be manually calculated without much effort -- you can find the equations in the Antenna Book -- but after spending years writing thousands of lines of code, I'm inclined to let the program do it for me.

I started with the example antenna Vert1, a simple ground mounted vertical of 40 mm diameter and 10.3 m height, at 7 MHz. It uses MININEC type ground, so there's no ground resistance loss, and the input resistance is about 36 ohms. To illustrate what I'm saying, I modified the antenna to have a feedpoint impedance of 50 + j0. I did this by lengthening the element to 11.45 meters and adding a 0 - j62 ohm load at the feedpoint. In real life, this would be a capacitor. The resulting feedpoint impedance is 50 + j0 within a fraction of an ohm.

Next, I made a second element of the same height and diameter but at X = 5.35 m, 1/8 wavelength away. I put a 0 - j62 ohm load at the feedpoint of this element, and also a source. This second source is a current source with a relative magnitude of 1 and an angle of -135 degrees.

Clicking Src Dat to see the source impedances shows the following:

Source 1: 17.5 - j31.82
Source 2: 20.57 + j30.67

Quite a change from 50 ohms. This is due to mutual coupling between the elements. So if you tried to get the current in element 2 by using a transmission line (and somehow did end up with the correct currents in the elements), the load end of the line would see 20.57 + j30.67 ohms, not 50 + j0. If you put 1 amp into the input of a 135 electrical degree 50 ohm line terminated with this impedance, what would come out? The answer is 0.85 amps, delayed in phase by 165.7 degrees -- not the 1 amp, 135 degrees you need. (This result comes from calculations using standard transmission line formulas assuming no loss.)

Before going on, change the Ground Type to Perfect (this won't change the impedances), and the Plot Type to Azimuth and run a far field plot. Although you'll never see this pattern in practice, it's what you usually see in texts and is useful for understanding the underlying principles. Notice that the front/back ratio isn't perfect, but is around 25 dB despite the perfect spacing and phasing. This is because mutual coupling has modified the current distribution along the elements. Although they have perfectly phased currents at their bases, the magnitude and phase change differently along their lengths. This can be a difficult or impossible manual calculation, so it's something you see with a program like EZNEC but not in graphs based on manual calculations. But it's real. You can improve the F/B by fiddling the feed system to modify the current ratio slightly to compensate. I suggest saving this pattern for future reference.

The antenna pattern with the magnitude 0.85/angle 165.7 ratio isn't relevant because if you did feed element 2 through a 135 degree line from element 1, it wouldn't see 20.57 + j30.67 ohms, because the current ratio wouldn't be 1 at 135 degrees. The current ratio affects the feedpoint impedances, and due to the transmission line transformation, the feedpoint impedance affects the current ratio. Both have to be accounted for at the same time. Again, the calculation isn't difficult, but again, EZNEC can do it. Remove the second source and add a transmission line from wire 1 end 1 to wire 2 end 1 (that is, from the base of the first vertical to the base of the other). For the line length, enter '135d' to make the line 135 electrical degrees long. (If you wanted to see the change in antenna behavior over frequency you'd have to use an actual length, and also change the load type.) Then run the far field pattern.

What you should see is a pattern with a distinct reverse lobe. The front/back ratio is 10 dB instead of 25 for the ideally phased array. The gain has increased 0.9 dB at the expense of a narrower pattern (which can be a disadvantage for a fixed array). If you saved the earlier pattern, you can easily compare the two by adding the saved pattern to the current one. This array has both noticeable gain and front/back ratio, which is why so many people using this kind of feed system mistakenly think they're getting the phasing they planned. But a look at the element currents shows a ratio at the bases of 0.92 at an

angle of -156.5 degrees, not 1 at -135 degrees. Is it a useful pattern? Very possibly. Is it what you planned? Probably not. If you used 75 ohm coax instead of 50, you'd get a different result. If you used quarter wavelength elements you'd have a different result. If you have ground loss you'd have a different result. And if you used two lines differing by 135 electrical degrees to feed the elements, you'd get a different result. At least with EZNEC you can get a good idea of what the result would be.

Using the Compendium article I mentioned in my last posting, you can calculate feeline lengths that *will* work. One set of lengths for this array, with these elements (having these feedpoint impedances) is 44.4 electrical degrees of line to the first element and 148.3 to the second, both 50 ohms. Note that the difference in length is 103.9 degrees, yet the element currents will end up 135 degrees apart, and with the same magnitude. I didn't run this model, but examples CardTL and 4SqTL illustrate the technique.

If you'd like to understand more about feeding phased arrays, I suggest taking a look at Chapter 8 of the ARRL Antenna Book. I believe it was the 15th Edition where the phased array material first appeared.

I'd just shorten it if it was only a matter of a few feet or so. You only have to be a couple of feet or so clear of the metal supports. If that's all you have to shorten it, you probably wouldn't even notice the difference. Traps would be a needless expense as well as reducing the effectiveness of the antenna. At the very worst, if you weren't pleased with the 'shortened' antenna, you could still add the traps -- but I wouldn't expect that outcome.

I guess it's a difference in semantics. If you connect your rig to one element, then from there connect to the second element through a transmission line, there's no length of line which will lead to equal magnitude, 135 degree phased currents. So if "fine tuning" consists of adjusting the line length, no amount of fine tuning will necessarily lead to a really good front/back ratio. (I say "necessarily" because you might get lucky with a good combination of element impedance, ground loss resistance, and feedline impedance and get close enough. But you might not.)

Sorry, I'd forgotten about the program. The original programs from the Compendium article can be downloaded as SIMPFEED.ZIP from ftp://eznec.com/pub.

Great story, Dick! It really makes the case for the unique on-the-air qualities of the venerable CW mode. Yep- it is definitely one of those "you had to be there" sort of things. :o) All the great qualities of the various digital modes not withstanding. I think that other hams who prefer to work phone or the digital modes are every bit as good as me, but those who have never grown to know and love CW just have no clue what they are missing. I work all these modes, but CW will always be my favorite. CW is going to be around on the ham bands for a good while longer.

>Phil speaks for himself on aol and he ID's as Phil.>

Perhaps. Perhaps not. It appears to me that "fractenna@aol" is such a public urinal of an address that we have no assurance of message authenticity whatsoever. Even if the lawsuit of his dreams depended on it, Chip couldn't prove who really wrote any given post that appeared there--regardless of who "ID" it. Face it! The "yellow" may be in the bowl, but--short of DNA testing--neither Chip nor ANY of us can prove who put it there because he has failed to properly control his password. That goes for those nasty little legal threats, as well.

Of course, as long as Chip pays the AOL bill and provides access, it is in the end, his "home address" and he's ultimately responsible for the things that go on there.

The world has developed several thousand standards by now. For what percentage of them have you seen the criteria for the studies, the unprocessed resuls and the detailed mehtods used to both get the data and how it was processed?

The IEEE RF-safety standards committee reviewed over 500 papers for the present version of the standard. For the next revision (or affirmation) they are reviewing over 1500 published papers. BTW, most of these papers were published in peer-reviewed journals, ensuring that they meet some level of scientific acceptability.

If you really are qualified to evaluate the studies, unprocessed results and detailed methods, I am sure that IEEE SCC-28 would be more than pleased to accept you as a member and accept your review and comment. They are looking for paper reviewers, last I heard.

And many of us pity the freebanders as well. They can have no sense of pride or accomplishment in their ham license. How can they? It is almost to the point that all anyone has to do now is open a box of wheaties to get a ticket. Now doubt Wall Mart will be carrying them at discount prices or as blue light specials soon.

Whether CW is more or less efficient than another mode or whether it is outdated or not is not relevant to the hobby. What is relevant is that CW at one time was the common denominator that literally held amateur radio together. Everybody paid the same entry "fee"...everyone went through the same hell to get the ticket...everyone respected the effort that every other ham had made to acquire that ticket.

The freebanders would have us accept the premise that anyone who believes in a strict set of entry requirements for the hobby is, in some manner, practicing discrimination or that we are elitists in nature. Nothing could be further from the truth and I suspect the freebanders know it. Their tactics are of the politically correct genre that is used to attack so many of the elements of society today. It is inappropriate for any individual to have achieved a status not held by everyone else. Therefore, that individual and his or her accomplishments are vane, even evil.

I would have considerably more respect for the freebanders if they were simply honest and forthright in asserting their true beliefs.

Try making the radials out of colored (insulated) wire the same color as the roof and lay them right on the roof. They'll be nearly invisible.

Yepp, the good old center fed Zepp .... I have used one for years .... I put up a G5RV for a while but went back to the Zepp .... only drawback, especially if you are using computer logging is RF in the shack getting into the computer. I have my tuner less than 2 feet from the entrance to the shack and a really good ground and it is not too bad on the computer except on 10 where the cursor jumps around the screen as I talk ;-)

289. "Converting" a commercial 42-50 mhz load to 6 meters

Newsgroup: rec.radio.amateur.antenna

I have an Antenna Specialists "low band" 42-50 Mhz 5/8 wave base loaded mobile antenna. These antennas, when new, are shipped with a cutting graph (which I do not have) so that the length of the radial can be tuned to the desired frequency in the spread.
My question...can this be tuned to 52 mhz by changing the length outside the graph?

I know I could play around with an SWR meter, but can the antenna handle it?

Oops! The holes in Chip's background are showing again...

> > Example? ART OF ELECTRONICS by Horowitz and Hill.

Horowitz is a nice book, good piece of work... I have a copy myself along with several editions of the venerable ARRL "Handbook", but do not be mislead... Horowitz is not an EE text!!!

Come on fellas... Horowitz is a neat book, but more of a comprehensive electronics hobbyist handbook, not an EE textbook.

I challenge anyone to name an ABET accredited EE program that includes Horowitz among it's recommended EE textbooks.
Horowitz could be used as supplemental reading for some EE courses, but it is definitely not an EE textbook.

With such opinions on EE text book material as espoused here on this thread, I can see that it is no wonder Chip N1IR has only managed to be employed teaching at a non-ABET accredited engineering school.

I'm glad that ABET is watching our engineering programs and keeping most engineering education programs at least plausibly honest.

Awesome. It was John Harrison, not Richard Harrison. John had stubborn opposition from the "not invented here" group, with their own selfish agenda. John had an even worse time trying to collect a royal reward offered to the first producer of a practical chronometer that had the accuracy needed aboard a ship to determine a ship`s position.

Richard Clark appropriately noted in an earlier posting, that success is as much taking the right measues as measuring right. Innovators often originate their own discovery and invention methods. How to measure is more easily taught than how to invent.

Best regards, Richard Harrison, KB5WZI

293. Lattin multiband antenna .....anyone build?

Many years ago a Mr. Lattin....W4JRW....developed and patented a novel multiband dipole.

This antenna is shown at:

www.wa3rey.com/lattin.htm

Lattin published these plans, and he also sold the antenna.

Has anyone used this antenna? Has anyone built or tried to build this antenna?

I would like to hear comments or experiences......

Ed:

Get real. No, no, and no.

None of this affects me or my amateur station operation, thanks!

Thanks for helping to protect us amateurs from onerous regulations, still...

I am personally not afraid of incidental exposure to RF in most casual/occasional circumstances. [Also, I don't look down the wave guide of an operating high power radar, or operate my microwave oven with the door off and my hand in the oven, or deeply enhale the gasoline fumes when I fill up my car gas tank at the self serve!]

But with all of the "hype" about this RF stuff in the media, etc... uninformed lay folks might easily be frightened into unreasonable actions.

I say, let's cool it on the scaremongering.

The average person is more likely to die in an airplane or train crash, wherein both methods of transport have smaller safety factors than exhibited by the new RF exposure regulations, than suffer any observable trauma from incidental RF radiation!

Ed, let's stop trying to protect everyone by well meaning, but misguided standards and beaureaucratic mumbo jumbo.

Come on, admit it, many standards groups are simply boondoogles perpetuated by the attendees of everlasting committees who, have their bosses bamboozled into believing that they are doing something useful, and who were sent to the committees in the first place by their employers simply to prevent anyone else from "winning" anything.

Been there, done that...

Reminds me of the early earnest Canadian DOC rule making about telephone jacks when they first came out. No free "male" jacks were allowed, in case someone put the jack in their mouth and might get electrocuted by the telephone line's -48 volts! Anyone ever hear of anybody putting a male telephone jack in their mouth and "buying the farm"???

What!!!

Stop scaremongering....

-Peter K1PO, Cary NC

However I do feel that

I have installed quite a few channel master tv antennas. I would go with the Yagi style antenna with a corner reflector on the back side. One that is at least 4 feet long should give you good gain and directivity. Get a name brand, like Channel Master or Winegard which are better quality than the Radio Shack (Antenna Craft) brand. I would spend a little more money on a better antenna because wind will wreck the cheaper ones in a couple of years.

If you get a booster, get a split one with the booster at the antenna and the power supply at the tv. Channel Master makes a good one. CMS 0064 is a vhf/uhf combination with a fm trap in it.

http://www.channelmaster.com/pages/u1.htm
Check out the uhf antennas (4248 model) and the Spartan mast mount preamps at this site.

Lee,

Lattin had an article in QST in the early 60's about these antennas. I built the 80/40M version and it worked very well. He did caution that trying to do more than two bands with one radiator would require a lot of cut-n-try.

Silver solder (as used for jewelry) is often available in five grades:

grade melting point
IT 1490F
Hard 1425F
Medium 1390F
Easy 1325F
Extra Easy 1270F

Sterling silver (7.5% copper) melts at 1640F and fine silver at 1762F.

That must be some soldering iron you guys use to work with silver solder!!
(I use a torch, myself; and nowhere near any electronics.)

"Soft solder" (sometimes with just a little silver in it) is a different
story, but this is definitely not "silver solder."

Looking for a few good used Bird 43 slugs. Could use:

5E (5W, 400 - 1000 MHz)
10E (10W, 400 - 1000 MHz)
50C (50W, 100 - 250 MHz)
50D (50W, 200 - 500 MHz)
100C (100W, 100 - 250MHz)
100D (100W, 200 - 500 MHz)
1000H (1KW, 2 - 30 MHz)
2500H (2.5KW, 2 - 30 MHz)

And perhaps others if the price is right.

Could also use a Bird 43 case, like the CC-1

Contact via e-mail at:

I tried two 75m hamsticks with the Lakeview connector for portable operations when visiting people. I was able to check in with local nets and made a few reasonable contacts but nothing impressive (as could be expected) but was impressed that it actually did work at all.

I'd like to chip in (pun intended) on this. I don't know of any way to track who downloads from the public ftp part of my web site. Actually, I'm more interested in how many than who, but if you want to put some effort into this, let me know. I'll be glad to help.

I believe that underneath the cover with the hole in it that the "tail"
goes through, you'll find a terminal strip with the same number of
terminals, which correspond numerically with those on the control box.

So just what sort of competence is it that a wannabe should possess? A birth certificate?

If they are
> competent people without a record of malfeasance, and pass a minimal
> test on rules and operating requirements, they should be issued an
> unresrricted license to full amateur priveleges in all bands, just like
> drivers are licensed.

Sounds just like the "test" that was once given to applicants in the 27 Mhz CB service. Care to show us the difference?

> The applicants already are owners of the airways
> just as driver applicants are already owners of the roadways.

Really??? Just like we all "own" all the "publicly owned lands" and "national parks". So why can't I just fence off my portion and park my camper there if it's mine"?

> The idea that a code or technical test is going to keep miscreants off
> the air is illogical. The character mix of licensed amateurs is
> certainly no better than most random groups. There are saints and
> sinners among coders and nocoders and among techies and the clueless in
> almost the same proportions.

THAT is illogical. Moreover it is simply incorrect. Anything that has been obtained free and without investment of even minor effort is held in disdain and to be valueless to the point that the holder is moved to the attitude of "so what, who cares if it goes?". Not an attitude conducive to causing to toe the line and act to protect and preserve it. This isn't rocket science nor news to behavioral scientists.

> The problem is vanity. Some amateurs prize an amateur license as some
> sort of credential of superiority. If everyone could easily get a
> license, the credential would lose value.

Pride in accomplishment does not equate to vanity. That you make such a linkage is revealing. It reveals that your view ham radio as merely a casual pastime that has no serious application to communications in the real world. Nonsense. A radio signal transmitted by a ham is no less a signal than that transmitted by the most important commercial or government station. It is just as fully capable of creating damaging interference problems to critical services. No hobby with such potential for creating widespread problems that are often totally obscure and unknown to the originator can be allowed to function on so loose a basis. To do otherwise is an abrogation of the FCC's mandate to protect the RF spectrum from abuse and misuse. It is the very reason for the existence of a licensing system.
Ham radio is unique in that respect if no other. It is clear that the influence of the far-flung outlawry on 27 mHz has permeated the thinking of a great many of the like-minded along with you. FCC has evidently decided that it is futile to attempt any serious control over so many miscreants, at least that seems the view of the current crop of FCC operatives.

> Exclusivity is needed to give
> class to the club. I pity them.

I pity you for your total misapprehension of the amateur radio service. It's about as wrong as it can be. And I know you're not alone, Cecil Moore being of like mind. I pity him, too.

Somehow it all comes back to a 20 WPM CW test. Those who do it don't think anything of it. Those who think they can't, criticize and say it's all for nothing. There's the revealing and pitiful truth.

Depends on whaere you look, that's all.

>As far as I can ascertain, CW used by hams on the
>HF ham bands has never saved a life. Is that badmouthing or just an honest
>statement?

It's incorrect. Morse used by hams in the ham bands has saved many lives. Most of them were long ago, of course, but they DID happen. Some were relatively recent - ask WB5RUE.

Your promulgation of false information is badmouthing. Lives have been saved by hams using Morse on the ham bands.
>
>You are like my Mother.

It isn't forced on anyone. Those who want the license pass the tests. Simple. No forcing at all.

>That won't happen as long as an HF ham is not free to choose his first mode.

No ham is forced to use Morse.

It's easier than ever before. Attractive is another story - that's in the eye
of the beholder.
>
>You don`t pass a horsemanship test to get an automobile driver`s
>license.

Nope - because most people today don't ever get near horses. Horse use on the
nation's roads is extremely limited.

But the use of Morse on the HF/MF ham bands is extremely common. So it makes
sense to test for basic Morse skill for access to those bands.

>Neither must you pass a test on the design and construction of
>automobiles.

But you do need to know something about how they work. Like how road conditions
affect stopping distance.

Your analogy is useless.

>Technology has made such tests no longer needed.

Only if the ARS is to become a service where only type-accepted, channelized equipment is allowed.

>unresrricted license to full amateur priveleges in all bands, just like
>drivers are licensed.

That's not how driver's licensing works in most states.

To drive a car requires passing a written and operating test. To drive other vehicles requires more testing. Here in PA, a basic driver's license doesn't allow you to drive an 18 wheeler or even a truck over a certain gross weight.

>The applicants already are owners of the airways
>just as driver applicants are already owners of the roadways.

There are about 250,000,000 Americans and about 5,000,000,000 human beings. Sit down and figure out how much of the radio spectrum between 3 and 30 MHz each of us can claim to "own".
>
>The idea that a code or technical test is going to keep miscreants off
>the air is illogical.

Not true at all. Look at what happened to another radio service that had no license tests. Utter chaos just a few years after it was created. The FCC has been trying to clean it up for at least three decades without success.

> The character mix of licensed amateurs is
>certainly no better than most random groups.

On what studies do you base that assumption?

>There are saints and

Not from what I've observed for 34 years.
>
>The problem is vanity. Some amateurs prize an amateur license as some
>sort of credential of superiority. If everyone could easily get a
>license, the credential would lose value. Exclusivity is needed to give

>class to the club. I pity them.

No, that's not the issue at all.

The problem is accomplishment. Some people value it, some don't. Getting a ham license used to be more of an accomplishment than it is today. Simple fact.

Here's an example:

I've run two marathons (26.2 miles) and a few dozen half-marathons (13.1 miles) in the past 19 years or so. I'm not a particularly good runner, but completing those races was an accomplishment - particularly the marathons.

Now suppose the folks in charge of certifying races (TAC) decided that a "marathon" should be redefined as 10 miles and a "half marathon" as 5 miles. Lots more people would be able to say they were "marathoners" but it would not be the same accomplishment at all. Doesn't mean the folks who run 10 mile "marathons" are evil or lazy. It DOES mean that the standards would be lowered.

Not at all. The discussion is about relative values over time. The Handbook that cost $3 in the fifties costs over ten times that now. The house that cost $12,000 back then costs eight times that now (in raw price). Add in the higher costs of taxes and insurance, and the Handbook hasn't inflated nearly so much.
>
>The point(s) is/ (are):
>

What "losses"?

The main reason the ARRL publishes is to be of service to amateurs. They have bills to pay, so the publications cost some money. Compared to similar sized engineering texts, they are dirt cheap.

>3) If the League didn't have the HANDBOOK then there would be a very severe

Sure - marketing and sales. Pretty smart folks in Newington. That's why I've been a member for 33 years.
>
>So not everything scales as a KWM-2 ;-)

Sure. The costs of producing a book like the Handbook skyrocketed. Particularly during the '70s and early '80s. The costs of producing electronic equipment have dropped.

We shouldn't even be discussing the Handbook, anyway. It's copyrighted material.

That wasn't CW used on the HF CW bands which was the boundary condition. Please
list some cases where CW was used by hams on the HF CW ham bands to save lives
that would otherwise have been lost.

> Your promulgation of false information is badmouthing. Lives have been saved by
> hams using Morse on the ham bands.

It wasn't false. Here's what I said: "As far as I can ascertain, CW used by
hams on the HF ham bands has never saved a life." That's an absolutely true
statement.

> How can you tell her the objective truth about the Bible, when only God has
> that knowledge?

Not so fast. Please prove that God exists. Why was the gospel of Thomas
left out of the Bible? Why was Revelations left out of the Greek Orthodox
Bible? Why does the Catholic Bible contain more books than the Protestant
Bible?

> It isn't forced on anyone. Those who want the license pass the tests. Simple.
> No forcing at all.

Are you saying the FCC doesn't have the power to influence, affect,
or control hams? Dream on.

From Websters: "force - power to influence, affect, or control"

Of course, the FCC forces, i.e. has the power to influence, all HF hams
to learn Morse code before they can use any other HF mode.

> No ham is forced to use Morse.

Every HF ham is forced to use Morse to obtain a license.

I've wondered about another way to feed these elements. How about backing up the feedline toward the source until a current maximum point is reached on each feedline. Transform both impedances to 50 ohms at the current maximum points. Add whatever coax is necessary to get the phasing right. What do you think?

If you're operating at HF, the pattern shape is determined primarily by ground reflections taking place well away from the roof. So the roof won't have much of an impact on the pattern. This is made even more so by the relatively gentle slope of the roof.

Which vertical?? Here is a paper available that compares several major brands.
This might be a better place to go first for some answers.

HF VERTICAL PERFORMANCE - TEST METHODS & RESULTS
Nï¿½AX and K7LXC are at it again - this time it's HF multiband verticals. Now you
can read an unbiased report on how they really performed. Antennas tested
include the Cushcraft R8, Butternut HF6V, MFJ 1798, Force 12 ZR-3 and V-3,
Diamond CP-6, Hustler 6BTV and Gap Titan. It's 64 pages of protocol, data sets
and summaries. Presented at the 2000 Dayton Hamvention. $17.00

Hopefully never. I keep hearing about all these poor technical geniuses being denied use of the ham bands and I keep asking who they are and it goes around the circle unanswered again. What poor techies?? I notice that your former boss isn't sitting on his butt and wringing his hands about being "excluded". That's the way it should be.
>
I've run into any number of wannabes over the years who told me "I'd like to get into ham radio but I just can't do the code . . " I have yet to run into one of those who had any technical expertise at all, they've all been Radio Shack clerks, scanner freaks, kids who get off on HTs, etc. who couldn't even handle Ohm's Law if their lives depended on it. All they want is a radio with a channel selector and a mic, anything more complex loses their attention.
>
How many nocodes have written articles which have appeared in QEX? Considering that they represent the largest license class in the service and that the license was designed to attract all the "technically competent potential contributors" without burdening them with a code test. There's the whole story, there ain't no other story.

Can't count the number of times I've played the game pretty much the same way quite successfully. 60-70 feet of wire up any way you can get it up and another 60-70 feet strung along the ground and that's all she wrote for 7-28 Mhz ops.100-150 ft adds 80/75. Less than a buck's worth of Home Depot insulated #14 thru the trees, whatever. No traps, no tricks, no nothin'. In my case I use any of several MFJ manual tuners because I run into high-impedance feedpoints which the auto-tuners don't like. I've found that using an MFJ-259B analyzer to tweak the tuner before putting the radio online greatly simplifies band-hopping and makes life easier for the radio.
>
Too many folk make too big a fuss over HF wire antennas, good antennas just ain't that big a deal. Unless ya just can't deal with it unless it comes from the factory with the PL-259 installed.

I will be pithy.

Have I been ivolved in book publication--and thus understand the costs and pricing structure?--yes.

Is the ARRL making some money from the HANDBOOK to over other losses in operations? Absolutely.

Do I have anything else to add, other than this accurate and factual perspective? Nope.

Do you understand what a copyright is and its application? Apparently not.

Have a good new year.

Wise precautions, all. I agree; I, too, am not afraid of exposure at the level of the standard, controlled or uncontrolled. I would be afraid for exposure at a rate at which I was absorbing 4 watts/kilogram of body mass for extended periods of time (ie, >6 minutes). Clearly, the exposure level needs to be set below that threshold.

>But with all of the "hype" about this RF stuff in the media, etc...
>uninformed lay folks might easily be frightened into unreasonable actions.

Absolutely, but the media hype has nothing to do with safe levels of RF, in fact, quite the opposite. I can point you to sites that offer some pretty bizzare "information" about RF exposure.

>The average person is more likely to die in an airplane or train crash,
>wherein both methods of transport have smaller safety factors than exhibited
>by the new RF exposure regulations

Are you suggesting that the safety factors be reduced to a level at which people die?

>Ed, let's stop trying to protect everyone by well meaning, but misguided
>standards and beaureaucratic mumbo jumbo.

Although I serve on the IEEE SCC-28 standards committee, I did not set the levels that are in the present standard. These standards were set by people whose expertise I believe to be much greater than mine, so I would not call the standard "misguided." If the level of the standard caused any significant difficulty for the Amateur Radio Service, I would be quite uncomfortable with the safety factors, too, but IMHO, the benefits of having regulations that define acceptable conduct, thus offering some degree of protection against the unreasoned "inquiries" of our neighbors, outweighs the inconvenience of having to spend a minute or two to demonstrate to ourselves that our station is under the limits.

I have talked to several neighbors of hams who had questions about RF safety, some of which were being raised wrt tower applications. In all of those cases, that neighbor came away from that conversation with an understanding that the RF coming from the ham's station was safe to them and their families. The very safety factors you are eschewing were the major part of their decision that

there was no safety issue at hand. If you can discuss any such conversations you have had, I welcome them.

>Ed, let's stop trying to protect everyone by well meaning, but misguided
>standards and beaureaucratic mumbo jumbo.

I do not see my role as protecting everyone from the "evil RF." I do see my role as helping amateurs to understand the rules, the reasons that they were created and the importance of doing what the rules say because it is important that the majority of hams are seen by the FCC as following the rules.

>engineering texts, they are dirt cheap.

I agree with both of you; ARRL publishes material that it believes will be useful to amateurs and prices them so that it can use the excess revenues over costs to fund many of its activities. Without the money from the sales of publications, either dues would have to be raised or some significant changes would have to be made in the scope of what ARRL does. If the dues were raised to cover the missing revenues, members would not renew, etc. Balancing its revenues between dues, pub sales and ad sales is a reasonable way to operate, IMHO.

Of course, if you would like to pay double your dues and not buy a Handbook, I can arrange to put the excess revenues in the ARRL Lab Test Equipment fund. :-)

>We shouldn't even be discussing the Handbook, anyway. It's copyrighted
>material.

:-) I can assure you that ARRL will not sue you for discussing the Handbook. I consider discussing its content to be protected both as fair use and as free speech. Under fair use, you could even quote short sections of it to further a discussion point without violating copyright, if my understanding is correct.

> Which one? When? How far apart were the ground stations?

CW through a satellite has already been done. There doesn't
exist the potential to do it again for the first time. Slight
changes in minute details don't matter.

> So? Why must it be the HF bands?

Because the Morse requirement is for HF and that was my original
question. Why can't I get an answer?

> Did Morse used by hams on the ham bands save a
> life that would have otherwise been lost in the WB5RUE case?

Morse code is not a *requirement* for VHF access so WB5RUE's
tale about using a VHF FM transceiver is irrelevant to answering
my question about lives being saved by hams using CW on the HF
CW bands.

> The information was false.

Nope, the information was about me and was 100% true. It is true
that I have never heard of a life being saved by hams using CW
on the HF CW ham bands. It doesn't mean it hasn't happened but
one would think I would have heard about it by now.

Jim, N2EY wrote:
"The anti-code "experts" tell us the military stopped using Morse for anything important long before the 1960s."

I don`t know when the military quit Morse. I know the Coast Guard no longer monitors for CW distress calls.

The military were large customers of AT&T, using leased 30-baud telegraph circuits. AT&T essentially declared the mode obsolete in the early 1970s and discontinued the service. My company was using the service over thousands of miles of leased circuits, not for Morse, but for BCH coded SCADA. We sued AT&T to continue the service and lost.

Without leased circuits for telegraph, the military was about finished with telegraph in the U.S.

AT&T had notified the FCC that it was discontinuing telegraph service and withdrawing the tariff offerings. The FCC agreed telegraph was obsolete and said AT&T was justified because there was no price for the service that could profit AT&T. Raise tariffs to cover costs and lose customers. Lower tariffs, and gain insufficient customers to return a profit. The FCC sided with AT&T against their customers, mostly government agencies and a few commercial users.

Western Union? It leases voice circuits as a communications supplier and as a customer of other carriers. I`ve heard FCC staff joke about its resident corpse, Western Union, and that was decades ago.

Long after AT&T has actually become only AT, Telegraph is dead. That`s why they`ve buried the cables, don`t you know? All this happened in the early 1970s.

Best regards, Richard Harrison, KB5WZI

Hi,

I live in the flat area about 50-60 mile from new york city.
I would like to buy a outdoor TV antenna to boot the TV
signal broadcasted from NYC..

I have several questions as follows:

1. what is the difference between
the antennas where the UHF element
are either vertical to the axis or V-shaped ?

top view:

```
| | | | / / / /
---------- or ----------
I | | | \ \ \ \
```

2. how many elenmet is appropriate ?
3. how long the boom is appropriate ?

Thanks !

Rus

Ed, that is not exactly what he's saying. Have you ever read "To
Engineer is Human"? Safety factors are one of the core features of
engineering.

To answer your question bluntly, yes, in a manner of speaking, that's
exactly what all engineers do. They nibble away at the bell curve of
failures until they reach a financially or socially acceptable limit
of harm. That's where the engineer's design will be most efficient.

If they did not do this, we'd never drive cars, we'd never operate
radios, we'd never use fertilizers, we'd never use drugs to cure
disease, and so on and so forth.

>>Ed, let's stop trying to protect everyone by well meaning, but misguided
>>standards and beaureaucratic mumbo jumbo.

>define acceptable conduct, thus offering some degree of protection against the
>unreasoned "inquiries" of our neighbors, outweighs the inconvenience of having
>to spend a minute or two to demonstrate to ourselves that our station is under
>the limits.

I think that any standard which takes apocryphal "non-thermal" effects
in to account, or which inserts its own arbitrary safety factors is in
fact misguided.

>I do not see my role as protecting everyone from the "evil RF." I do see my
>role as helping amateurs to understand the rules, the reasons that they were
>created and the importance of doing what the rules say because it is important
>that the majority of hams are seen by the FCC as following the rules.

I don't think anyone's suggesting that you are. I do suggest, however, that the standards committee is running amok with some well intentioned ideas. However, I think they're falling for the fallacy of "if X exposure is bad, then X/10 must be better, and X/100 ought to be outstanding."

The assumption that proportional decreases of exposure will produce proportional decreases in injuries is bogus. It's like assuming that if the law of the land reduces the definition of intoxicated from .10 to .08 blood alcohol level that you will get a lower death rate on the roads. Below a certain point, nobody takes it seriously.

We all know that beyond some socially acceptable point we'll get diminishing returns. The RF exposure standards have been pulled mostly from studies which merely document effects, not actual injuries. So we already have standards which are arbitrarily stringent.

The problem is that we already have many places where the older 10 mw/cm^2 standard is met but the new exposure standard is not. Do you think people will take the new standard seriously when they've been working under the old one for all these years without injury? Do you think it would be politically acceptable to weaken the present standard with all the fear-mongering in the media?

I don't. That's I'm so jaded about this RF exposure standard.

I realize that I'm whining. I can't do anything about this standard. It exists. It's policy. Hell, now it's even the law of the land. I just can't help thinking the whole thing is a bunch of hooey.

Rus Maybe check out the Winegard TV Antenna pages at URL:
http://www.winegard.com/offair1.html

Fringe Area Specifications like yours at URL:
http://www.winegard.com/caspecs.html

Look around your neighborhood to see what other installations are
receiving.

The element "vertical to the axis or V-shaped" have to do with
directivity -- but wouldn't worry about it.
Number of elements and boom length determine gain and directivity -- the
more (longer) the better -- but you need to determine the model you need
based on what other closeby installations are receiving.
I have had Winegard Antennas in the past and they are excellent.

A local installer may be able to advise the model you need.

Good Luck

What about using coax long enuf to just get out of the shack? My assumption is that the coax will stop some of the RF in the shack problems.
I've been using a 102' doublet fed with cheap (RG58U) coax and am thinking of switching the feedline to ladder line. I'm thinking of using the coax out of the tuner just to get out of the shack. Then go to the ladder and up to the doublet. I am looking at a book to try to decide if a balun is in order.

Hello, "H" and "V" beams both should work equally well, it mostly a design factor for matching the antenna to the feed line (75 ohm coax or 300 ohm twin lead) and should be worried about. Most manufactures for TV antennas list consumer grade antennas by miles they are good for. A general rule of thumb I heard a LONG time ago (we won't go into that please) was get an antenna rated for twice the distance you need. So an antenna rated for 100-120 miles should give you a good quality signal for 1-2 TVs. Beyond 2 TVs, go with a pre-amp, either mast mounted (preferred) or a inside, possibly a distribution type. Also a pre-amp can at as a lighting protector. It is better to lose a $20-30 pre-amp than a TV. Go to a GOOD TV parts supplier. They will have access to a good selection of antennas and pre-amps. Not worst case, but you can do better, Radio Shack does have a good selection of antennas, pre-amps, rotors, cable, antenna mounts.

Through an amateur satellite, yes. You said it was done through a non-LEO military satellite. You said you were "sure". But you can't tell me which one.

> There doesn't
> exist the potential to do it again for the first time. Slight

I gave you one, but you ignored it. Many lives have been saved by hams using Morse on the ham bands. You want exact details, go look through old QSTs.
>

There are NO "HF CW bands". Not in the USA, anyway.

The answer to my question is obviously "yes, Morse used by hams on the hambands saved lives in the WB5RUE case". You don't want to admit that fact, so you don't answer the question.
>
> > The information was false.

I told you there were many examples of it in the past. So now you have heard of a life being saved by hams using CW on the HF CW ham bands. Twice.

> It doesn't mean it hasn't happened but
> one would think I would have heard about it by now.

Why? You're not omniscient by any stretch of the imagination. Heck, you never heard of Ten Tec until I told you about the company. Some of the best CW ham gear ever made, but you had no knowledge of it. Probabaly still don't.

Nope. I didn't write that. You're mistaken. Again.

Of course, Ed. My point was that Chipper singled out the Handbook as
a "cash cow". I have no idea what it costs to produce that book, or
what it cost to produce in years gone by. I DO know that it's a
fraction of the cost of typical engineering texts. And it contains info
specific to ham radio.

> Without the money from the sales of

Simple marketing - you price at the knee of the curve.

Down through the years, the price of a Handbook has tracked the cost of
a single year of ARRL membership pretty closely.
>
> Of course, if you would like to pay double your dues and not buy a

Handbook, I
> can arrange to put the excess revenues in the ARRL Lab Test Equipment
fund. :-)

That reminds me - better go check my membership status. Don't want a
hole in the QST collection.

You know, if Hq really wants a "cash cow", please consider putting the
older Handbooks and other classic League pubs on CD-ROM, just like QST
and QEX. Better yet, print repro versions (clearly identified as such).
Start with the 1949 Handbook....

Better yet, put out a book containing all of the "Rotten Radio"
articles, the "Flippin" stories, and "Dixie Jones Owl Juice". They are
all still relevant today.
>
> >We shouldn't even be discussing the Handbook, anyway. It's

AT LAST! Somebody got it! The duck just came down!

>I can assure you that ARRL will not sue you for discussing the
Handbook.

I am breathing easier already. Whew! I was afraid somebody would want
the basing diagram for a Type 80, and I'd be facing a moral, ethical
and legal crisis.

> I consider discussing its content to be protected both as fair use
and as free
> speech. Under fair use, you could even quote short sections of it to
further a
> discussion point without violating copyright, if my understanding is
correct.

Works for me!

Some trivia that is sort of connected:

I heard somewhere that you cannot copyright a title. I could write a
song and call it "Stardust" or "Stairway To Heaven" or even "The
Liberty Bell" and copyright the music and lyrics, but neither I nor the
owners of the better-known versions can copyright the title.

The "ARRL Handbook" used to be called "The radio amateur's handbook"
(sic - only the T was capitalized) but back about 25 years an imitation
appeared with the same title. So the League changed the title to avoid
confusion. I was miffed that somebody would copy the title of Handy's
handy handbook.
>

There is an old story, probably true, that a friend of Art Collins' tried to get Art to sell him one of the Collins ham receivers "at cost". (Most versions of the story say it was a 75A-4). Art refused. When pressed, Art finally had to tell him that if he sold the friend one "at cost", the price would be MORE than he would have paid at a dealer! The friend took the hint and just bought one through conventional channels.

There was also at least one home made 75A-4, but that's another story.

I've heard there is an advantage to the forward swept elements, but I
can't really remember why. I don't think the difference is large at all.
They usually rate tv antennas in "miles". Say 70-90-120 miles etc. Don't
get one too close to the edge. If I were 60 miles away, I wouldn't get
the 70 mile version, I'd get the 90 or 120.
You need a little overkill to account for weather/ducting effects,etc ,
wet twin lead if used. The bigger the better in general. It's cheaper to
buy a big one first and be a happy camper for many years, rather than
get a too small one, and having a slightly noisy pix at times. Then you
end up buying the bigger one after all. I would think UHF more critical
than VHF. Most combo antennas seem to use a corner reflector/log type of
deal for UHF, with the swept elements for VHF. MK

No need to go thru all that. Just run ladder line straight from the tuner to the antenna. Why ruin things adding coax to a setup like that? With the ladder line, no balun is needed. Most tuners have a 4:1 inside for ladder line anyway. RF problems in the shack are caused from weak decoupling of the antenna to the feedline when coax is used. If you run coax you need a good balun at the feedpoint, but this is not a good multi band setup compared to using just the ladder line unless you are paralleling dipoles or something like that. You will have large losses on some bands with the single 102 ft antenna feeding with coax. Real high SWR and coax don't mix too well. But the losses using ladder line with a high SWR are not too bad. Coax stops nothing as far as rf. In fact, without a proper balun from the coax to the ladder line, you will be causing problems not stopping them. With ladder line all the way, you should have very little rf problems overall. I know I didn't here using a mfj 989c to a center fed 30m dipole used from 30-10 meters. Had no rf problems on any of those bands with that antenna. With my coax fed dipoles I use a coax choke balun to help cure common mode problems. Grounding really helps nothing. May bandaid the problem, but fixes nothing. The real problem being the antenna /feedline decoupling. Or maybe fundimantal overload. But thats not the antennas's fault. That just being too close to the strong rf field. Nothing you do will fix that except moving the antenna farther away, or fixing the effected gear to have better shielding to rf. MK

Ground antenna for Apollo.
This wonder may be viewd on my WebPages

Click on the picture of me for a minibio and a few links to NASA including
the site at Tidbinbilla.

Loads of fun
Interesting your mechanical calibration methods I managed to produce a
device producing 12 V/ micron whilst working on the EMI Scanner. I still
have the prototype in my junk box. One day I might get around to finding a
use for it connected with Ham Radio.

I can make no fault with that, I think that what has happend is that so much more technical work is now going on that much of the shoddy work hides the few brilliant accomplishments going on in odd corners. High precision is not a commercial money spinner, so most of it goes on out of the lime light. That said I would like to see the general standard benefit from the rigour that was developed and is now lost from the very earliest days of the emergence of good physical laboratory practices. It would be nice to see Hams taking a pride in the precision of their measurements and applying that care to all that they do, especially in contests and other activities on air.

This is interesting.
Do you think that such a standard would be within the realm of the ham shack?
Can you think of a method whereby this standard can be used to calibrate a noise standard? i.e. Noise Temperature / noise power in a known bandwidth. perhaps bolometric bridge.

Seems to me one could sweep the frequencies using a FSM to find the
maximum gain point and fine tune from there. I'm always looking for
easier methods, like varying the length of the feedline to tune the
antenna system so I don't have to build/buy a 500w tuner.

When did rescue agencies ever monitor the ham bands as a standard practice?

From history we find examples of rescue summoned by radio telegraph at sea which douibtless saved hundreds of lives.

Radio watch on the CW distress frequency has ended. Why? There are better ways to call for help now. To save lives, what works best should be used. Hoping someone is on-frequency and paying attention within radio range is inferior to calling on a satellite phone for help. Plain voice and no code needed. CQD, SOS, and May day are understood by speakers of many languages.

Best regards, Richard Harrison, KB5WZI

I know that CW probably saved lots of lives. I am trying to narrow
the set of information down to where CW used by hams on HF bands
saved lives. I don't disagree that it might have. I just have not
seen any evidence yet. I have read QST since the early 50s and I
don't recall it ever happening.

That is understandable considering the topic heading, for a moment I was hoping to prompt the thought in contributor and lurkers head, "wait aminute what exactly are we trying to acheive?" that point seems to have become lost here and there along the thread.
We are attempting to launch a wave that will propogate to a distant point of our choice.
Does the buterfly flapping its wings in New York have any effect upon the weather in London. well that really depends about what happened before.

If we retrace our steps backwards along the wave path from this imaginary point on an ideal wave to the origin the wave geometry and strength depends upon what came before, finally we reach the origin, what is the ideal wave pattern of oscilating voltages and currents going to be. Does it really have to be related to the earth at that point, what has changed so radically from the remote ideal wave to this feed point. It seems that it is the geaometry of the device that we are using to launch the wave. Popular because it is easy to construct is the counterpoised vertical, Marconi used it and gave his name to it. Doe sthat mean that we are not barking up a tree. The enginuioty of the human mind has devised a loop antenna.

So her we have a device on one hand that is mostly Voltage operated and on the other hand a device that is mostly current operated. Both methods require extremes of low resistance because they are operating at boundary conditions.
What we need, (and at this time I have not the slightest ide what this thing would look like), is some device that will launch the wave without requiring either high current or High voltage to transduce power from the transmitter into space.
Of course by reciprocity the same structure will also be a receiving

antenna.

> The mechanics here are simply the Z's found at the interface or
> boundary. That is, the wave in the air travels through a Z of more
> than 300 Ohms

Something of the order 377 Ohms per sqaure I think.
At least a bit of RAM (RADAR ABSORBING MATERIAL) with that sort of spec has
a very low reflection having absorbed most of the ray.
This works out to (u0/Eo)^1/2 according to Ginzton, Silver, et.al.

>whereas when it encounters the earth (in any form) it is
> subject to a mismatch because that earth Z is substantially less than
> free space Z.

The boundary condition?

> It is the mismatch that controls the mechanics of
> reflection and even if the ground is lossy. If it presents a
> substantial Z differential to free space, then very little power will
> be lost to ground (the mismatch reflects most of the power and very

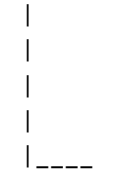
How is this measurement acheived?

> Thus the quick answer to your question above is - yes - ground
> Resistance (Z) is significant to the process of reflection. the
> significance of that ground resistance is found in the differential,
> not in the absolute value. The greater the differential the better.

Interesting, so
as R(earth) approaches zero
377/ R(earth) approaches infinity
or no power loss.
or simply Power(earth) = I^2 R(earth) = 0

Now does this go the other way
as R(earth) approaches infinity
377/inf approaches zero.
And power dissipation is 377 I^2
or all of the power is in the wave.
This would indicate that the higher the wave is above the Earth the better
it goes.

Returning for a moment to a practical AE at long wavelength in an urban
garden. just how high is high enough. In other words would it be better to
site the active element a bit higher so that the stub to ground does not
place such a stringent requirement upon Earth conduction?



```
_____ (~) feed point
| <stub match also used to elevate AE
|___e_a_r_t_h__r_a_d_i_a_l_s_ whatever____
```

perhaps some lumped reactance in this side,
but not sufficient to limit the loading current.

> (I would add that it necessarily follows that earth Z should be as low
> as possible - if you can control that factor.

Moving the feed point just a little away from the earth will transfom the
feed requirement. I suspect that even a little will help.

> Contrariwise, a
> exceedingly high earth Z would perform the same job just as capably,
> but attaining a very high Z is for all practical purposes - far more
> difficult, if not downright impossible.)

Yes we Earth bound creatures have to accomodate our environment. :)

> Now to the second part of your question (part B). Most neophytes
> presume that the ground condition at the base of the antenna is
> responsible for the low angle launch characteristic. It is not.

I might expect the ground resistance is the factor that limits load current,
and nothing else.

> Ground conditions near the antenna (within the first wavelength) are
> responsible for MATCH conditions far moreso than launch conditions.

So a small stub in the earth side of a vertical below the feed point would
help to increase the required earth impedence for satisfactory loading, and
feeder VSWR.

> It is the far field ground that matters more for launch conditions and
> again this strictly a function of the Z differential.

This supposes that the vertical is sufficiently high above the more distant
mirror will produce correctly phased waves to combine with the main wave
thus producing the beam launch angle. As the AE height increases so the
angle becomes shallower and a greater distance at ground level is acheived.
Yes you have drawn quite a clear picture of that physical process for me
thank you.

>The higher the
> mismatch to free space, the greater the reflection (the cleaner the
> mirror). If you could extend those 120 radials out 10 wavelengths,
> then you may drastically boost that Z differential (by driving down
> the ground resistance).

I suspect that the major effect of increasing the length of the ground
radials is to increase the maximum possible AE feed current and therefore
notionally increase the efficiency of the feed. Since shorter radials are
already acheiving high efficiencies of feed current the increase in radiated

power will go almost un-noticed. Especially far field signal strength monitoring will now be subject to factors having a greater bearing upon the propogated wave and power.

> However, this is a very difficult requirement
> to be met (your 10M vertical would have to sit in the middle of a
> football stadium sized ground field - scale that to 160M to discover
> the sheer size demanded!).

And at 136 kHz even more so. :)

> One compelling proof of this is found in the excellent reports of
> mobile operations within short distances from a shoreline. Water is
> not a very good conductor, but its Z is sufficiently low to present a
> very high mismatch to free space borne waves and thus presents a very
> good reflection surface.

How for instance would a vertical sited at say Pevensey marshes near to the shore line, compare with and identical structure on top of the Cliffs at Ventnor.
Both structures will launch over a sea water mirror but the greatest differnce between the two structures will be the angle of incidence at the point where the wave first meets the surface of the sea.

>The near field earth conditions dominate the
> match, and the far field earth conditions dominate the launch angle.

I think that is what you have caused me to see. thank you.

> In all practicality we can control near field earth conditions far
> better than far field earth conditions (except when we purposely
> choose a site based on these considerations such as locating near a
> ocean shoreline, lake, or marsh).

I guess I better look for a house on a cliff top near the sea, there should be some cheap ones going about now because of their propensity to "fally in the water."
Applogies to Sir Eccles

> Thus to answer your question in the context of this thread, shorter
> radials may be effective for a MATCH condition, but have no effect in
> the launch condition. The same answer could be applied to lengthened
> radials (that is, until they are some 5 to 10 wavelengths long) too.

So what one might expect to see is an increase in loading current but no reported increse of signal level at a remote point. :)

One could see that ther are the seeds of disagrement between the operator of the transmitting station and the receiving station.

However as the primary objective is the signal level at the distant point we must take the receiver operators word for the quality of the communications channel.

Hi Richard,

Hmm, forgotten some of our First Class teachings, eh?

May Day (from the French for help me: m'aider (?)) is well known, and relates to situations that pose a danger to a person.

Securitï¿½ is also a call that relates to a situation that poses a danger to property (if I recall correctly). In fact, I've rarely seen this discussed and may have fallen into disuse (or simply ignored by Francophobes).

Hi Cecil,

As I use to admonish my students in the Navy, RTMFM (Read The
Meticulously Formulated Manual).

Your method still smacks of nailing jelly to a tree. As Roy points
out, when you excite one, the other, or both, it is a new game every
evolution. This has all the hallmarks of taking a very long time.

Sorry if I wasn't clear. It's not unexplored, but in no way has it been explored to its full potential.

> I've been
> writing applications for PCs for years that have debug messages beeped
> in Morse code (the lowest common denominator for when the system hangs
> and the screen freezes).

Excellent! I recall a story where some medical equipment would beep "SOS" in Morse if it was nonfunctional.

But man-machine interface goes far beyond error codes. And there is also the "other direction" - human telling the machine what to do. I can't use a touch screen or keyboard safely while driving, but I could use a Morse key then.

Basic point is that the possibilities have barely been explored. Lots of potential applications - but some folks simply refuse to see them.

381. Homebrew Antenna sugestions for 462mhz please

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-03 22:51:41 UTC
From: tomfree <tfreeman@blueridge.net>
Message-ID: <t57b9vhq3fl2f3@corp.supernews.com>
Source record: 173050

I just started using the Cobra PR-1000 to communicate with the house when out on my farm. I would like to add an antenna mounted on top of the house to make communications more reliable when at the extremes (distance wise) of my property. We are talking rolling hills and woods. The house is near the middle of the tract of land. It also has a tin roof and I was not sure about the effects of this on any installation. The antenna would be mounted on a pole about ten feet down from the crest of the roof at one end of the house, the pole will extend above the crest. Since the antenna will be fairly small at these frequencies (462Mhz) I wanted to try my hand at building one. Any suggestions would be appreciated.

Tom

I would recommend analysing this antenna with appropriate software first
to have a certain imagination of the frequency range. Go find someone
owning EZNEC, AO, YO, NECfWin etc. and see the properties of this piece
of aluminium. After analysing you maybe find an easy way to convert it.

> I would of course feed it with 75 ohm coax to the 300 ohm balun on the

If you have known properties you don'T have to count on these 'cheap'
baluns.
Build a new feed (don't need to be difficult/expensive) and use the
amount of power you like.

I use the MFJ-16010 for a portable tuner with my Icom-706. It is a very small package and ideal for QRP, although its claimed power rating is 200 watts. It is an L-match constructed from a tapped toroidal inductor and a small air variable capacitor. I use random wires exclusively when I travel, and it has unfailingly tuned everything I've put up. I have observed no problem with saturation of the core at the 100 watt level, and I have consistently received good signal reports from all over the world. I highly recommend it.

Never ran into one. Of the several dozen electronics techs and EEs I know who are hams I can only think of three who don't have 20wpm Extras and one of those has an Advanced ticket and the other two are Tech Pluses going back to the 60s.

None. The discussion is about nocodes, I'm not a nocode. I wasn't excused from taking the code tests so that I could "advance the state of the art if it wasn't for the damned code test".
>

> I know nocode techs who
> write articles for IEEE publications, hold RF engineering patents,

So? What's any of that have to do with ham radio? Absolutely nothing. The unaswered question still remains on the table: "How many nocodes have written for QEX?" The

flagship underlying argument for minimizing or eliminating code tests has been to open the doors to to the technically astute who would contibute their expertise to advancing the state of the art given no annoying code tests. Along with "accomdations" and "credentials" cometh responsibility. A triple PhD who squeezed in with a nocode ticket and has done nothing beyond squeezing in is an insult to the service and a joke of a ham.

Myself, I can't tell a lot of difference in using the 4:1 or not.
Nothing magic about the ratio thats for sure.
The one in my tuner is pretty stout though. It's pretty big and wound
with teflon etc. I don't think I've ever gotten it warm hardly. But I
don't run ladder line all that often. I think a 1:1 just about as good,
just as long as you have some type of balun to handle balanced lines.
"Instead of hooking to coax connectors" etc. To me, if he has a balun in
the tuner, using coax and a balun between it and the ladder line, kinda
a waste of time unless there is some reason for it. Myself, I'd just run
the ladder line the whole way and be done with it. So far here , I
haven't had any real problems with the built in baluns. But my tuner is
rated 3KW. Of course thats wishful thinking in many cases, but it's
balun is still fairly beefy. But most my everyday antennas are coax fed.
I use the ladder line for feeding weird stuff that may not have a 50 ohm
feedpoint. MK

The toroid for the 4:1 balun in my MFJ949 is about the size of a quarter.
My current balun toroid is four inches in diameter. There's no comparison
in the current handling capacity.

It is possible to fly across the Atlantic Ocean in a 747 instead of
in the Spirit of St. Louis but nobody cares.

> You know what the Elser-Mathes cup is?

Nope, it must not make the front page of the Madisonville Meteor.

> What, exactly, did you do to "research"?

Most of the QSTs for the past 50 years, all my ham radio reference books,
and the world wide web. The Texas A&M Library is next.

> First time you use the words "asking for help" about this. I doubt you really
> want help or information.

If I didn't want or need help I would have not asked the question. Why
would I ask a question if I already knew the answer?

> You're not struggling.

You say I am ignorant. Therefore, I am struggling. Please enlighten
me with your knowledge like you did regarding Ten Tec.

> >I didn't say CW-only bands.
>
> You implied it.

Nope, you inferred it. What I was trying to do was narrow the question
down to the HF ham frequencies normally used for CW. If I were calling
for help using CW, I would call for help on the frequencies normally
used for CW, wouldn't you?

> You have not asked for help before now.

Uhhhhhhh Jim, asking a question is what the normal person does when he
is asking for help. How do you ask for help?

> You'll pull it apart in typical Cecil fashion.

I give you my word, I am simply asking for information that I have been
unable to obtain by myself.

> Now you can pick that apart all you want, Cecil. But now you have heard a true
> story of human lives saved by hams using CW (Morse) on the HF ham bands.

I don't want to pick it apart. Thank you for the story. Was that published
in QST? I wasn't reading QST in 1937 so I missed it.

Don't know about you, David, but I can read CW through almost any
QRM except another narrow band signal right on the same frequency.
I hear people checking into nets when they can't make it with SSB
and the weak CW signal is readable through the SSB KWs.

I owned a T-10 Tennadyne LP for quite a few years. I loved it! It covered 13. thru 30 mhz, maintained a F/B of greater than 17 dB over its entire operating range and showed no worse than a 1.7:1 vswr. I had it up 72' and it was fed via 175' of coax. I used it mostly in DX contests, and never had any problem working whomever I called with 500w output.

It held up mechanically quite well through five major ice storms. The sixth storm caused some problems with the boom to element mounting of the largest/longest element, but was repairable. This antenna was 10 el on a dual 24' boom. It weighed 55 lbs. My Yaesu G1000SDX rotor had no problem handling it along with an elevation rotor above the T-10 with 2x22 el K1FO horizontally stacked 70cm yagis and a single 12 el K1FO 2m yagi.

I sold it when I moved. I should be putting up a new tower in the spring and I plan to buy another Tennadyne. This time, I'm downsizing to a T-6 (12' boom, as I recall). I found their service and delivery to be perfect. The antennas are built well, and they peform as they should.

With the T-6 what I was looking for:

1. Low maintainenece.
2. 4 to 5 dB gain
3. consistent F/B > 15 dB
4. Good match
5. Relatively short boom length.
6. Low weight and wind loading.
7. Good value for the dollar.

All of these criteria are met by the T-6. I have no hesitation recommending their line of antennas. If I were more adventurous, I would go back to the T-10 or even a T-12, but I just don't have it in me any more.

Well, based on everyone's input, I think I'll just run 450 Ohm ladder line to the 102' doublet straight from the tuner. I have an older MFJ tuner rated for 300Watts. My old Ten Tec only puts out about 90 to 100Watts anyhow.

This 102 footer fed with coax and no balun actually seems to work pretty good on 80, 40, and 20. My rig doesn't work to well on 15 and 10. I think the antenna is too short for 160M. Now all I need is a warm, dry day, and I'll unroll some ladder line.

HI:
When I ran VHF in Michigan, my lot had many 100' maple trees all around the antenna site. I often wondered if the trees had any effect. The only thing I can say is that there was no difference between myself and a friend that talked to regularly if the trees has leaves or not on 6m. I take that as an indication on 6m the trees had little or no effect. I also had a 450MHz link from my shack to another friend for a split site repeater we ran. There the link signal went up about 3db when the trees lost their leaves. So on 450MHz I'm sure the trees had an effect. On 450MHz rain and snow also had an effect.

I believe every word you said. But that is true with the system you
are using. Others may not be so fortunate. The matchbox was designed
to match ~ 500 Ohm balanced line, of course it will tune beyond that
range depending upon frequency and so forth.

I have and use a matchbox. In my case it did not provide a good enough
match for my solid state rig on several amateur bands. My solution was
to include a "T" type tuner in series with the matchbox and doing that
everything works fine.. and I can also get on 160 with this
arrangement. However, this setup does require a bit more knob
twisting... But what the heck, real hams twist knobs :-)

Maybe, maybe not. I have a CCRadio and Select-A-Tenna. The main limitation on pulling in distant stations seems to be local stations that are on the same frequency as distant stations. The local stations wipe out any distant stations on the same frequencies. So receiving distant stations is relegated to whatever gaps I have in local frequencies, so this can be a fruitless exercise, unless you live in a rural location without a lot of local stations (I'm in a big metropolitan area).

Having said all that, my $1200 JRC NRD-525 with its amplified antenna doesn't really pull in distant AM broadcast stations any better than my $150 CCRadio, and my little $20 Sony Dream Machine does about as well as my CCRadio.

The tuning on a CCRadio might be a little smoother than on the GE SuperRadio, but the SuperRadio has the same 8" ferrite core built-in antenna that the CCRadio does, so I don't know that you'll gain that much.

Bob

http://www.io.com/~n5fc/notebk_ant.htm

The zigzag antenna design at the above URL led me to wonder if zigzag radials are a viable option. I also read somewhere that radials do not even have to be symmetrical. I also read that the use of many 1/16 wavelength radials can still yield respectable performance.

Are zigzag radials a viable option? If so, less space is needed for the antenna (especially important for apartment dwellers like me). Furthermore, the wire radials are less cumbersome to deal with.

I find it hard to believe that people have room for 1/4 wavelength radials for vertical antennas on 160m, as this means 130-foot radials extending outward from the antenna. The zigzag design of the notebook antenna sounds like a possible solution for apartment dwellers who need radials for a short vertical antenna.

So how important is it that radials be straight? While I am certain that deviation from straight radials reduces the effectiveness of the antenna ground, I am not certain whether this reduction is slight or gargantuan.

But can an effective radial be made of helical conductors? As I have pointed out before, my Cliffdweller slinky dipole stinks. Exactly why is a helical antenna design inefficient? (As a BSEE graduate, I'm not that afraid of equations.) And what makes a particular radial set more effective than another set given the same number and length of radials?

Source record: 172937
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx

I keep hearing about the use of a counterpoise, or a length of conductor connected to the ground (of the transmitter, tuner, and/or antenna) terminated by an insulator at the far end.

Are zigzag wire counterpoises (whether used as radials for a wire antenna or as an RF transmitter ground) viable solutions? Again, a zigzag configuration takes up less space and is less cumbersome to work with. Again, I refer you to:
http://www.io.com/~n5fc/notebk_ant.htm

I have been told to use a 1/4 wavelength wire counterpoise as an RF transmitter ground if the cold water pipe and the 8-foot buried metal rod are not viable solutions.

What happens if I use a shorter counterpoise? How much less effective is such a counterpoise as an RF transmitter ground? (This could be an issue at lower frequencies.)

What happens if I use a longer counterpoise? Can you use a counterpoise designed for 40m (33 feet long) on 10m (which would be a full wavelength long)? Would a long counterpoise be even more effective? Or would it radiate unwanted RF?

What happens if I use multiple counterpoises?

I have heard that one should avoid having ground loops when
constructing an RF transmitter ground.

What exactly is a ground loop? What are the ramifications of one? (Does
it cause unwanted RF transmissions?) And how do you avoid ground loops?

Jim, N2EY wrote:
"The number of hideously communications and physically disabled folk learning the code and finally being able to express themselves by some truly inventive means is growing by leaps and bounds."

That struck me as so funny, I couldn`t quit laughing for awhile. Thanks, Jim.

Is Jim characterizing radio amateurs? Well maybe he meant other handicapped people. Maybe tragedy has comic implications, at times.

What does this have to do with test requirements for amateur radio? It`s only desperation to find some merit in an outmoded device, Morse code, used to exclude people from the amateur ranks. It`s been used as hazing, or passwords and secret codes used by children in their secret societies.

Using the tragic to persuade that morse should pervade the ham bands is not new. There is the old stroke victim story. The speechless patient could only communicate with the medic, who happened to be a ham, by squeezing his fingers in Morse code.

It`s a real stretch to make practical conclusions from the extraordinary.

Best regards, Richard Harrison, KB5WZI

Better than no radials. Yep, the mass of radials at the base of the
antenna the most important place, so many short radials will do pretty
well. Zig zagging is no real problem. Not as good as straight, but much
better than none.

I string mine out just about any old way. I don't have 130 ft straight
line, so I have them run along the fence lines, around the base of the
house, along the lawn, etc. Most are making turns somewhere.

A helical antenna needs capacitance at the end to work well. A slinky in
itself does not satisfy this. Add a fairly long wire leader to each end,

in addition to the coil part , and I bet it comes to life. I use quite a few helical antennas for mobile, but all use long stingers. A must for decent performance. And if you dump the narrow windings and put a larger lumped coil in, all the better. MK

Hi Tom,

They would precede the sampling as precision rectifiers, hence the need for GHz unity GBW to work at HF (this band restriction may be less than the original poster intended tho'). As for a source, I am steadfast in the products from Analog Devices whose Op Amps I confirmed to my customer's needs when I designed the Flight Data Recorder.

As an example of one of their products randomly selected:
>The AD8009 is an ultrahigh speed current feedback amplifier with a
>phenomenal 5,500 V/ï¿½s slew rate that results in a rise time of 545 ps,
>making it ideal as a pulse amplifier.
visit their page at:
http://www.analog.com/industry/analog_processing.html

Gain of one configurations with a headroom of noise gain will provide bandwidth, stability and low distortion.

My notion probably pushes more design into the probe than was there previously (what we in software call feature creep), but the technology should be able to support my notion at a reasonable cost to the amateur.

So what? Knowledge in itself is worthless unless it's applied in useful directions. I know several useless PhDs and so do you.
>
The "relationship" involves the basic fallacy behind the nocode ticket which dropped the code test in order to attract more technical expertise to the service. That maneuver may or may not have done that, there is no way to dipstick those data. Two points: What is a nocode PhD EE contributiong to the service unless that PhD is working on technical issues which contribute to the state of the art? Which was a cardinal and ongoing excuse for dropping the code tests. The mere possession of credentials means squat unless those skills are used to the benefit of the service. A PhD on a machine isn't "contributing" any more than Joe the eighth grade dropout plumber on the frequency. Once again which nocodes with or without academic credentials have contributed anything to the volume of ham technical literature? They've had ten years to justify the dropping of the code tests so that they could "upgrade the technical content of the service". Where's the BEEF Cecil? Ed?
>
Second point being that the nocode ticket has drawn a helluva lot more Joes than it has Termans which in turn has resulted a huge dumbing-down of the service overall. Which is exactly the opposite, predicted result vs. the transparently bogus rationale used to justify the creation of the nocode ticket.
>
I don't have a problem with nocodes as such, I'm glad they're out there populating the high bands, I have a bunch of nocode buddies. I have a big problem with those who continue to try to couple nocode EEs with anything actually useful to the service beyond getting paid by their employers to design the radios. Which EEs probably do in many cases without any ham tickets.

My favorite AM radio is the old zenith transoceanic. Has a good loop built in the top. Wide as a barn door, but they sound great. I still have an old 1958 model sitting under the table here. But I'm afraid to use it lately, because the caps are drying out, and I'm trying to conserve the tube life. "They are getting kinda hard to find" without paying 2 arms and a leg. My old drake R4 is a pretty good AM radio, but I don't have the low freq converter , so I can only drop to about maybe 900kc or so before my preselector is too far out to be usable. But what it does get is pretty good up in the upper end of the band. MK

So what nothing. The statement is true, that's what. To bar otherwise qualified people from HF ham radio simply because they don't know Morse code hurts amateur radio. Would you refuse to be rescued by someone who didn't know Morse code? Aren't 1000 emergency operators superior to 500 emergency operators even though 500 of them don't know Morse code? The vast majority of the hams who know Morse code are not dumb enough to use it for emergencies anyway.

It certainly did at Intel in Chandler, AZ. I suspect that is multiplied by any number of large electronics firms all over the nation.

> What is a nocode PhD EE contributiong to the service unless that PhD is

Answer: Whatever he chooses to contribute, just like you, me, and Ed.

> Where's the BEEF Cecil? Ed?

What have you contributed to amateur radio that a nocoder cannot contribute? If I didn't know Morse code, would that prohibit me from having three antenna web pages? Would it prohibit Ed from being an RFI expert? Exactly what changes happen in someone's brain when they learn Morse code that turns them into a more worthy and more valuable person? Does your wife know in what low esteem you hold nocoders?

> Second point being that the nocode ticket has drawn a helluva lot more Joes than it
> has Termans which in turn has resulted a huge dumbing-down of the service overall.

Exactly what has been the effects of this "dumbing-down"? Nobody was dumber than I when I passed my 13wpm Morse code exam in the early 50s at 13 years of age. Introduction of the Novice Class License in the early 50s certainly dumbed-down ham radio. But obviously, you were already a genius when you passed your first ham exam.

Seems to me, Morse code has had much more of a dumbing-down effect on amateur radio than have electronic engineers. There is an organization of men with large sexual members. Seems Morse code symbolically fulfills that function in ham radio by separating the men from the boys, so to speak.

> societies.

Thats kinda a stretch there. Morse code has never been used as a means to exclude anyone. It was first used to enable hams to know if they were interfering with another service or emergency from what I hear. Not to mention being the heaviest used mode. If a person refuses to learn the code to get a test, they are the ones excluding themselves, not the fcc. The reason being all have to pass the same test. The same way we all have to pass the written. The written could be called a hazing by a few I'm sure. I know myself, I had much less trouble learning the code than I did learning theory. Why? Because there is so much more theory to learn. The code is 26 letters, 10 numbers, and a few others used for periods, etc. Now, you tell me, Why would it be harder to learn appx 40 characters of code, compared to learning all the theory needed to pass the extra? "I'm talking about learning enough to really pass it, not just memorize the questions". I was doing 18 wpm when I took my novice ticket in 1977. But when it came to theory I was a real dumbass. Still am, it could be argued...:(It's taken me 20 plus years to get where I am now from scratch. Much longer than learning the code. I've never worked in the radio field, EE, phd, ad nausium... I'm just a regular "started from scratch as a SWL" dummy that does this only as a hobby. I might could have faked my way thru the extra test in maybe about 1985-1990 or so, and thats still a good ways past 1977 when I first started. But I ended up getting it in 1997 I think. 20 years later. And I still failed the extra written the first time. It's weird, most say the advanced the hardest, but I flew right through that one. I found the extra harder. So to me, it would be backwards, the written was more of a hazing than the code. I found the code a total piece of cake. It's just how the person looks at it I guess. BTW, although I won't lose any real sleep if they drop the code requirements, I still think it's a good thing for hams to know, even at only 5 wpm. It can come in handy. And that speed is so slow to be useless for any real use, but takes very little time to learn. That is unless the person has a self induced mental block about code. Now, if the rest of the world dropped the code as far as the ITU etc, and the USA kept it anyway, then you might have a point. But thats not the case so far. You HAVE to know code to work HF. So far anyway. It's not just something a bunch of guys down at the ARRL or somewhere just cooked up to exclude people. It's obvious they want

even more people in. I think they would endorse the end of code in about 3 seconds if they had the chance. IE: end of worldwide regulations requiring it. I'm sure the FCC could care less one way or the other. MK

>
I obviously went over your head. A primary pretext for the creation of the nocode license was that hordes of techies who didn't want to deal with code tests in order to become hams (i.e., don't care enough about ham radio to do a little work, God forbid) would jump into ham radio and upgrade the base of technical skills and make contributions to the state of the art. Thus were born specific expectations which would justify eliminating even the 5wpm code test. Ten years later of course no such "contributions" have been made and the whole nocode "technical contributions" apologist crap is a failed mindless snicker as was predicted ten years ago.
>
The FCC didn't drop the test requirements for Extras in order for us "to enable contributions to the state of the art", I didn't slide in with any onus on me other than passing the test. I've met the "expectations".
>
As far as where the contributions are coming from glom a copy of QEX and track down the license classes of the authors and get back to me when a nocode gets published.

Can't speak to those two in particular, but have experience with the SGC-230 family. My advice is to either:

1. Install a knife switch(s) and manually ground the antenna and disconnect it from the tuner when not in use in lightning season

2. Install a relay to do the same, powering the relay from the 12V line to the tuner so that when the tuner is powered down, the antenna is disconnected and grounded.

Source record: 172956
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx

Hello Jason,

Lay your radials straight or bent, of no particular length
or depth. For a given amount of wire prefer more short
radials to a few long ones. Stop when you get to about 6
radials, do some listening tests on known transmissions, add
another 2 radials, do some more listening tests. If you
can't detect any difference in received signal strength
between 6 and 8 radials fire up the rig and call CQDX.

Download program ENDFEED in a few seconds from the website
below.. Not zipped up. Run immediately.

Judge the relative radiating efficiencies of vertical or
inverted-L antennas used with a differing number of radials
of differing lengths shallow-buried in different types of
soils.

This little, easy to use program will also tell you the
inductance and capacitance settings of the T or L-network
needed to match the feedpoint impedance to a 50-ohm
feedline.

To home-brew your own tuner or loading coils download
program SOLNOID2. It's so easy !

And if you've ever wondered how a tuner + coax + balun +
twin-line + dipole + ground works, download program VARNEY.

Makes handbooks, annuals and magazines obsolete.

Bill, download program VARNEY from website below. Takes only
a few seconds. Run immediately. You will find there's
little or nothing to choose between one dipole length and
another when used with ladder or open-wire line. Keep the
coax short and use a choke balun wound on a 2" diameter
ferrite ring.

441. Re: HP4815A vector impedance meter question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-04 19:26:19 UTC
From: tom_bruhns@agilent.com
Message-ID: <932ioeqgj1@nnrp1.deja.com>
Source record: 172961

Hi Richard,

The original probe is really pretty simple, conceptually: sample the current and the voltage with very low jitter and at a relatively low rate. Buffer the sampled output back to the main box (in a way that specifically matches the system design). As they say, the devil is in the details.

I tend to keep pretty well abreast of what modern op amps can do, but I sure don't see much place for them in this situation. (Why would you "precision rectify" before sampling and lose the phase info??)

As I see it, the question is something like, "is it practical to homebrew a probe that will plug into a stock HP-4815A box to replace a non-existing original probe?" It might be possible, but in the 4815A manual you won't find much info on the parts in the probe, specifically the current sampler transformer, a couple current-mode baluns, and a delay line. It seems to me if you want to keep to the spirit of the question as I've stated it, you probably shouldn't have to supply external power to the probe, and the output should interface directly with the 4815A main box. It seems to me it would be a step backwards to make things more complicated to use than the original.

If the question instead is, "can one homebrew a vector impedance meter with capabilities similar to the HP-4815A?" then maybe there should be a different thread on that. In fact, there's already one over in sci.electronics.design just now, similar freq range and all.

Cheers,
Tom

Message-ID: <y7456.152$1G4.2260@newsread2.prod.itd.earthlink.net>
Source record: 172960

By no means do I have a killer station, in fact, it's downright cheap, but it does work and it comes embarrassingly close in performance to the "big boys" for the things that I do (75, 40 & 17 meter ragchewing).

My used Yaesu FT-890AT was a terrific bargain at $450 and so was the MFJ-989C and the Ameritron AL-80A "one lunger".

My antenna consists of a Van Gordon "All Bander", which sounds just like what you will be running when you feed it with 450 ohm twin lead. Presently, the apex (inverted vee config.) is about thirty feet off of the ground with the ends down somewhere around four feet. It is a temporary set up, but it works far better than any of the commercial, multiband verticals I've operated. Maybe I can talk the brother-in-law into raising the apex and ends a bit during his next visit (thanks, Bob!).

As far as RF in the shack goes, I don't have any more in the shack than what I had with properly installed commercial, multiband verticals with short coax feedlines. Back in those days I had a smaller lot and was able-bodied, so the quality of work was at least passable.

If you can, try to make a nice long route to your shack with the 450 ohm twin lead. You might then be surprised to learn that you will be able to load up on 160 meters.

From: tom_bruhns@agilent.com
Message-ID: <932joi$r9m$1@nnrp1.deja.com>
Source record: 172962

O!...does that mean it will be short??

I suppose I should not have expected any different, but the "technical" info on the site you mention does seem a bit ... umm, ... non-technical? For example,

"Finally in 1994, the first CFA was brought into regular service, by the Egyptian Radio and TV Union. It was a modest device, handling less than 10 kilowatts on the medium wave. But it was only some 7 metres high - a traditional antenna at that power would have needed to be many times higher."

Oh? How interesting! How low would the power have had to be so that a traditional antenna could be 7 metres high? I wonder how high a traditional antenna for 1 megawatt at 20kHz is. Magic seems magical only until you understand how it's done, hmmm?

Thanks for the pointer, Reg. My prediction is that CFA antenna proponents will continue to try to keep them "magical", and the antennas themselves will continue to work as antennas always have... :-)

Cheers, and Happy New Year,
Tom

You missed the point, Mark. Legal CBers are HFers and don't have
to know Morse code. In fact, CW is illegal on CB, isn't it? :-)

Point was, of all the HF stations, aren't hams the only ones
required to know Morse code?

Well, the accused may have been fined for something else, but all CBers can legally operate HF because that is where 27 MHz is in the radio spectrum.

My, ABET accredited, school uses Horowitz as a reference in the
mandatory, terminal design course (student must demonstrate the
ability to design and build, not just analyze). I also suggest the
ARRL Handbook to the students and our library keeps a copy of the
Handbook on reserve.
Looking back many years, I received my first formal understanding of
electronics from reading the Handbook. My first experience with
intolerance was having a socialist teacher confiscate my copy of the
Handbook. 73 Mac

Is this the company? This is the info from the ARRL TIS database at
http://www.arrl.org/tis/tisfind.html:

Wilson Antenna, Inc.
1181 Grier Drive, Suite A
Las Vegas, NV 89119
Tel: 702-896-0399
800-541-6116
Fax: 702-896-0409
Email: wilson@wilsonantenna.com
http://www.wilsonantenna.com/
Products and Services
ANTENNA>ANTENNA MANUFACTURER;

If they don't have a manual, see also:

http://www.arrl.org/tis/info/pdf/9206067.pdf

For an article about a few of the companies that sell reprints of equipment
manuals. You can also use the TISFIND database and type "equipment manual"
as the search criterion or scroll down to the category list and pick
PUBLICATION-EQUIPMENT MANUAL OR SCHEMATIC.

Thanks, Mike- your posting has been the best laugh of the week, so far!
Just a case of mistaken identity, and it sure got the no code/pro code
rumble going again :o)
Poor KB1EVA. That must have been a horrible experience for his family.
Perhaps a good lesson here, however-
Question authority, challenge 'experts', investigate personally,
form your own informed opinions!
Ya gotta love those rumor mills, though- eh? :o)

456. Mobile Top Hats

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-04 22:59:32 UTC
From: Cecil <Cecil.A.Moore@IEEE.org>
Message-ID: <3A550054.82F9864D@IEEE.org>
Source record: 172976

I realize that this is the Morse code and guns newsgroup but hope
that no one will object to some antenna information.

I promised to do some measurements for someone but I don't remember
who or what thread - so here it is. My HS-1600 with top hat can be
viewed at: http://people.delphi.com/cecilmoore/mobnow.htm

It is tuned for 75m and note that only 2/3 of the coil is engaged.
Someone asked me what height of stinger was equivalent to my top
hat. I had never approached it from that angle before so I did
some measurements leaving the position of the HS-1600 coil fixed.

The top hat is located at eleven ft from the ground. There is no stinger
above the top hat. If I remove the top hat and install a stinger
to resonate at the same frequency, a twelve foot stinger is required.
That makes the antenna 23ft from the ground - slightly illegal.

The resonant frequency with the top hat is 3.95MHz. The resonant
frequency without the top hat is 8.5MHz. The top hat shifts the
resonant frequency by 4.5MHz. Since minimum inductance on the
loading coil results in maximum field strength, the effect of
a top hat is as close to something for nothing as one can get
with mobile antennas.

Please advice your friend to go to a good lawyer.
To my opinion he should be able to recuperate some of the damages inflicted by fractenna@aol.com (Fractenna) by starting this threads.
This case looks so clear that it should not cost him any money because the lawyer will do it on a no cure no pay bases.

Source record: 172977

> ... The matchbox was designed
> to match ~ 500 Ohm balanced line, of course it will tune beyond that
> range depending upon frequency and so forth.

The manual for my Matchbox says that it "is capable of
matching a 52 ohm coaxial transmitter output into resistances
ranging from approximately 25 to 1200 ohms for balanced
lines and 25 to 3000 ohms for unbalanced lines and antennas".
The real limitation comes with the reactive part, which they
say can be "several hundred ohms at the higher frequencies
with somewhat less reactance compensation at the lower
frequencies". That's where a switchable section of line can
help. Cecil, W6RCA, is a big advocate of this method.

I am forever thankful for EZNEC and MicroSmith which
allow me to easily predict what impedance I'll have at the
shack end of the transmission line.

> I have and use a matchbox. In my case it did not provide a good enough

>The Boston papers report this guy lives in Haverhill and sure enough there it is in the flesh as KB1EVA.<

Nice detective work "Phil"! Of course, since nobody can prove who actually wrote this mis-information and posted it via "fractenna", responsibility ultimately resides with the the person who pays for that address and controls access to it.

For my own part, I was mislead by the post--and I apologize deeply to Mike, KB1EVA, for any inconvenience my own commentary may have caused. The fractenna site has been "dark" for the last couple days, and think I can see why.

Interestingly enough, the Dover Rochester Times, a small NH local, recently stopped printing the names of apprehended suspects appearing on the police blotter when the Rochester NH police department refused to provide offenders' addresses. The reason? Because, with no address given, any other person in town with the same name might be unfairly subjected to social ostracism and harassment for an offense they didn't committ.

Guess the Times knew what they were doing! Fractenna did not.

But they are also not supposed to talk over 150 miles away. Also using type accepted xtal controlled radios.
To drag CB into this is kinda silly. Besides, all the people I know that run 11m wouldn't be caught dead with a "cb" radio. They are all using ham rigs, usually better than mine. Thats how the guy I know about got caught. He was in between channels. Dead givaway. Almost all the people I know that hang out on 11m and are serious about radio do so because they don't want to take the code test. Except for maybe the truck drivers.
>
> Point was, of all the HF stations, aren't hams the only ones
> required to know Morse code?

Sure, but we still commonly use it. And we are the only ones that can build our own gear that could possibly interfere with other stations. If Joe ham that transmits "cw only" hears Sam ham spewing 40 kc worth of garbage up and down the band, how will Joe be able to tell Sam if Sam can't copy code? Thats the reasoning behind the rule. Whether it's still a valid rule is not the point, the point is it's not a hazing ritual as Richard suggests. MK

Thats why I was careful not to give his whole callsign or name in my original posts about it. You could have two guys the same name in the same town. Although myself I was convinced he was probably the right one, you never know. Looks like he wasn't. There are lots of Mark Keiths. There was a Mark Keith in Mass. in the 1690s. He was the first that I know of. If I do a people search on my name, I get a whole boatload of me. All in different places. But all originated in Scotland many a moon ago. Most of my other half all came from England. There must be 100's of me around the world. Thats a lot of ugliness to spread around if they all look like me. :/ MK

Reg,
It's been a few months since I checked on the CFA antennas
in use at a number of stations. At that time, the one in
Austrailia was the most documented installation. The actual
performance of the CFA at that time was nothing close to the
projected specfications. It was so bad, in fact, that the
station had gone back to using their 'normal' antenna, and
demanded that the CFA be removed from their building. The
test results and measurements by the designer had been proven
false, and in general, the whole idea was suspect.
Until there is quite a bit more evidence to the contrary, I
think the CFA can be written off as a scam.
'Doc

I assume right now you're using a built-in antenna on the PR-1000. If you use a reasonably short length of low-loss line between the radio and your roof-mounted antenna, you probably don't need much of an antenna up there. I'd suggest a simple "ground-plane" antenna. A web search should turn up several ideas for how to build one, but if not, ask again here. There's a LOT to be gained by keeping the two ends of your radio link line-of-sight or nearly so, so getting practically any antenna up high like that is a big plus. But do use good line and minimize the length of it. 3dB would be a good maximum line loss to shoot for, I'd say, which will be fairly easy with 60 feet or so of RG-8 foam line or maybe 35 feet of RG-8X. Those are "soft" numbers...a bit more won't kill the advantage of height in the clear.

There are antennas you could build with considerably more gain than a ground plane, but they're more trouble and most would take instruments to get tuned up correctly. A ground plane should work if you are simply careful about getting things the right lengths and connected correctly.

Cheers,
Tom

John,

Mine will not tune 50-Ohms (resistive) on twenty meters! I really doubt that the ranges given is true for all situations. I think (and haven't proved) the manual is using the best situation possible for those those ranges.

Understand I'm not poor-mouthing the matchbox just stating that it is not a panacea. Nor is it a cure *all* for the coax to balanced line transitions.

No. I didn't write that.

>That struck me as so funny, I couldn`t quit laughing for awhile.

Disabilities are not "funny".

>Thanks, Jim.

I repeat: I didn't write it.
>
>Is Jim characterizing radio amateurs?

No. Jim didn't write it.

The author was talking about REAL people with REAL disabilities who are using
Morse code to communicate. That's a good thing.

>Well maybe he meant other
>handicapped people.

He wrote "disabled", not "handicapped".

> Maybe tragedy has comic implications, at times.

The tragedy is that you missed the point entirely.
>
>What does this have to do with test requirements for amateur radio?

A little. Not much.

Back up in the tread and see what was being discussed.

Cecil claimed that Morse code had reached 100% of its potential. He said there
was nothing new to be learned about it, and it had no new applications. He
challenged me to come up with some. I did.

Not talking about test issues at all.

> It`s
>only desperation to find some merit in an outmoded device, Morse code,

It's not outmoded if people are using it and finding new uses for it.

>used to exclude people from the amateur ranks.

That's not what Morse is used for. You can get a ham license with no knowledge of Morse at all. Ever listen to the HF ham bands?

> It`s been used as hazing,
>or passwords and secret codes used by children in their secret
>societies.

Nope.
>
>Using the tragic to persuade that morse should pervade the ham bands is
>not new.

The discussion was about new uses for Morse. The test issue is a dead duck. The FCC has reduced the test requirements as far as they can without a treaty change. The treaty won't change before 2003. End of story.

And the reason the FCC reduced the tests (both code and written) is simple: Less admin work for them. 5 wpm code means no more medical waivers. Fewer license classes mean fewer upgrades. Less paperwork, less cost. Simple.

> There is the old stroke victim story. The speechless patient
>could only communicate with the medic, who happened to be a ham, by

No, there is nothing we can do about ground except create an
artificial one from radials. Stubs or gamma matches do not change
ground, they change the transform of its Z (Earth Z is as lossy before
as it is after).

>thank you.
It is more the height of the current max (which of course is a
function of the height of the antenna, but in reality ALL currents are
responsible - not just the current max). Think in terms of light rays
and imagine a source roughly 1/2 up a quarterwave structure. This is
the origin of your "ray" for the purposes of observing where it
strikes ground for that principle reflection. If you are interested
in a 10 degree launch angle, your ray must be depressed 10 degrees
below the horizon. Follow that ray to ground and you find it strikes
it more than 5 wavelengths away from the antenna. This is the point
of reflection and THAT ground is the principle controller of the
efficacy of reflection. This is because the boon of verticals is the
combination of the reflected ray and the direct ray. If you cannot
support a reflected ray at the Earth/Free Space boundary, you have
lost the 3 dB boon.

>TNKS 73

Hi Gary,

I am responding principally to the concern of low angle radiation and
if any improvement comes by virtue of radials. You have identified
that there is a grain of that issue in simply improving the radial
system(stronger signal in general is found at all angles). Yes, on
those observations this is true and you are already aware that may not
be very significant.

But back to improving the launch angle, here is some data to consider.

As you've already noted, free space Z is 377 Ohms.
I will now offer the Earth Z for various conditions:
frequency dry soil wet soil ocean
300 KHz ~150 ~25 1 Ohm
3 MHz ~180 ~50 7 Ohms
30 MHz ~180 ~65 20 Ohms
300 MHz ~180 ~65 30 Ohms

We now enter into the poorly understood (for this group) concept of
the "Brewster Angle."

This is also known as the "Critical Angle" and represents that angle
subtended by the ray and Earth, beneath which there is little
reflection and maximum absorption. This is what robs the horizon lobe
of its maximum gain at very low angles. That is, there is still a
principal ray 10 degrees above the horizon, but the reflected ray 10
degrees below the horizon MAY be absorbed by Earth and offer no
contribution to the signal strength at the other end.

The Z ratio of Earth to Free Space has a log-linear relationship with
this critical angle. If Both Z's equal then you cannot expect a very
good radiation boost by reflection for angles less than 45 degrees.
Here is a summary:

SWR lowest angle of reflection
1:1 45 degrees
2:1 22 degrees
3:1 ~15 degrees
4:1 ~12 degrees
5:1 ~10 degrees
10:1 5.5 degrees
50:1 1 degree

You will note that to obtain a 50:1 SWR between Free Space and Earth, then Earth must be Ocean below 3 MHz. If you want to have a reflected ray combine effectively with a direct ray for angles of 10 degrees you will need an Earth Z 1/5 of 377 Ohms. That is, 70 odd Ohms, which means that Earth must be wet soil. You will note the trends above and find that for VLF/ELF, the Earth/Free Space interface is as effective as a copper boundary. This condition is reflected (no pun) in the upper atmosphere and creates a waveguide condition which creates very strong earth bound signals that span the globe (this why they use this frequency for submarine communications).

This all leads us back to the topic of radials, and of course we see that short radials have nothing to do with the reflection point in the remote distance unless they are VERY long and VERY dense (which is already a contradiction). If such were the case then Earth Z would appear to be on the order of 1 Ohm (we can only hope) at that remote point.

The manuals and some parts for the old 70's Wilson amateur antennas can be obtained from Majestic Communications (Maco) here in Memphis. They have quit building the line, but still have an unknown amount of parts. FWIW, I bought a bunch of formed element_to_boom clamps (similar to the Hygain brackets, only slightly longer) from them for a good price. My last purchase was a year ago, but I'm sure they've got more.Their web site has all of their current production CB (ugh!) antenna manuals in PDF format. If you need the older ham stuff, call them at 901-794-9494.

I am unaware of the actual circuitry, so I assume a situation where it
appears to be much like the SWR circuit we find in the common meter.
I recall there being an issue of finding exotic semiconductors that
seems to be missing from your premise above - that is what I am
attending to in bringing Op Amps into the mix. Otherwise, what's so
difficult about building the probe except perhaps special order coax
that goes to the probe? If this were the case, I would say that is
simply a marketing requirement not an engineering one.

>
>Cheers,
>Tom

Hi Tom,

As you've already averred, this is actually a simple circuit (but it does have some exotic components). As such, there is no issue with the over riding design, but with the replacement. It is the replacement issue that is frustrating the original poster (either of the probe or the probe components).

The precision rectifier DOES NOT discard phase information, in fact it is eminently superior in maintaining this as the fastest traveling portion of the curve is at the zero cross over, and every diode on the market DOES NOT sustain any signal at the cross over, but rather some 0.3 to 0.6 volts above. This is why this circuit is called a "precision" rectifier. There is far more accuracy in phase measurement at the zero crossover than at the peak which is extremely difficult to find, but very easy to construct. I hope you understand the distinction I am making in that seeming contradiction. I am aware that the 0.3 volt cross-over would serve as well, but my understanding was that there was an issue of replacing semi-conductors. What I offer is a substitution that improves over this problem (if it in fact exists).

Perhaps if I were to expand. My supposition would be that there would be clippers and separators that followed the precision rectifier that would provide the basis for phase angle recovery and incident signal level. The trick here is to observe the complete circuit that performs this operation, not just the probe in isolation as it is only a partial implementation (again, I am unaware of the specifics, but in my career at the bench I have seen what I describe above used to perform these very operations).

My solution was offered as a means to bring the meter back into operation. As a Ham, I, myself, would not shy away from this task - in fact I would embrace it as a technical challenge. However, I have a considerable base of experience in this regard which gives me the confidence to persist to a successful conclusion. I will be the first to admit that this is prone to many problems (already acknowledged as the possibility of building a free running oscillator). This is no guarantee that it is a good solution for everyone, and is not a sift to separate the men from the boys.

Jim, I am sorry for mistakenly attributing something to you. I don`t know who wrote it.

Jim did write, or so it appears on my screen:
"The conclusion is simply that Morse has new uses. It`s not "outmoded". That`s all."

Commerce, the military, and other agencies have abandoned Morse. They communicate more than ever, but with other codes and voice.
Today`s voice and data replace Morse. American Telephone & Telegraph Company no longer offers telegraph circuits to anybody, Armed Forces, included. Their name is phoney. It should really be just the AT Company. The Western Union operator no longer occupies a corner down at the railroad depot. No Postal Telegraph messenger boys deliver "wires" on their bicycles.

Morse is no longer stylish, that is, Morse is outmoded.

Best regards, Richard Harrison, KB5WZI

This is simply another ploy of USING someone else's reputation (or
creating one) to serve the last paragraph above. This TRASH was
started for one purpose only, and it wasn't with regard to any greater
human interest issue. All members of this board already note the
allusion made in the last sentence which is in the same vein of a
consistent character assassination. Also note the characterization is
an invention to create a greater illusion of monstrosity AND THEN to
suggest that this is the TYPICAL perception of Hams by the public.

All may note my repugnance of this quote for what it is: TRASH, which
was made some time ago and slammed by the same poster with a veiled

threat wrapped in the ignominy of a perverted sanctity. There was absolutely NO REASON to introduce this subject in an antenna forum.

I think there is a victim here, and he is fully justified in taking legal action against the source of these deliberate speculations and self-serving statements noted in the quote above.

Source record: 173016

Out here in the Pacific Northwest, where we grow trees to hundreds of feet in height, a number of enterprising hams have placed HF yagis on rotators in live trees. I have personally assisted my friend Phil Heintz, K7XS, in putting his cushcraft A4 into a 100 footer. K7IR has also done work in trees with hf beams. Usually, they trim the top off to get a solid trunk area to attach the rotator assembly and prevent the upper tree branches from interfering with the rotating elements. Tree climbing is very tricky and dangerous. Only climb them if you know what you're doing and take the proper safety precautions. Or hire a professional tree surgeon to do the climbing for you. Or hire a bucket lift, staying out of the tree and going right to the top. A bucket lift can take the fully assembled antenna right to the top too. Good luck! K7JY, Seattle.

Hi Gary,

Your signal calibration method would be of interest, yes. Pass it
along. I've done a lot of reviewing of technology writing, mostly for
Gravity detectors, high temperature super conductors and related
technology patents so I will be steeled for your tome.

As for a shack Volt standard, you might peruse the surplus market for
Zener based gear (not all that uncommon by now I would 'spect). Years
back they were just arriving as transfer standards.

As for a noise source, I use a constantly illuminated Photomultiplier
Tube with a 50 Ohm Load. The trick of course is in the constant
illumination - use a constant current fed LED (high voltage, big
resistor is one way - I'm sure you can take the ball on this one).
This has been an ad-hoc standard (not NIST) for quite a while now

which will give you noise from DC to GHz. You can stretch your imagination and creativity with this angle. And you use a rare term here - bolometry. I've burned up a few bolometers in my time. The PMT and a variable filter should provide you with any spectrum you might want to experiment with.

> Lee Carkenord KA0FPJ

I tried modeling it.

I started out with a 10M section. After a lot of tweaking segments and segment alignment to get stable, realistic results, I added a 12M segment, expecting to get two resonaces somewhere around 10M and 12M.

I only got one resonance at about 16MHz.

Anyone else tried modeling this thing? Results?

Jim Pennino

Source record: 172871

Okay. I operate exclusively on HF -- mostly CW on 20 meters. So, please excuse my ignorance of VHF and UHF.

Anyway, I'm thinking of getting an IC-706 to run in my travel trailer. As you know, it will also operate on 2m and 70cm. So, I'm thinking that if I carried a 5 watt handheld while off romping in the wilderness I could stay in touch with the xyl and she with me.

The question is, What sort of range could we expect? And, what about under conditions where the line of sight is interrupted like an intervening hill, mountain, canyon, etc.? Considering what I'm wanting to do, which would be better, the 2m or 70cm band?

Thanks, Pete KA�TZK

PS. Yes, I know that she'd need her own license. She'd be happy to do that, of course.

> drivers are licensed.

You clearly don't understand why the Amateur Radio Service
exists, per reguilations.

Set aside the code issue for the moment and read your post.
Now read 97.1 b, c and d - which you are supposed to know,
and which knowledge you say new hams should be required to
possess: "and pass a minimal test on rules ..."

97.1 a - e provide the basis and purpose of amateur radio.
You are supposed to know that. 97.1 b, c and e require technical
competance. You're recommending throwing away 60% the reason
for the existence of the Amateur Radio Service when you say people
should be granted full priveleges based on passing a minimal test on
rules and operating requirements.

Esentially, you are arguing for the disbanding of the Amateur Radio
Service, whether you realize it or not.

Nonsense! When the government first handed us all frequencies "200
meters and down" the bandwidth of a CW signal was the same as it is now.
And I did NOT say bandwidth of a spark signal.
From there we have steadily lost spectrum as commercials found the high
frequencies useful and found commercial uses for them.

He realizes full well what he is arguing for and has been doing so for the last year. His hatred of things CW and those that support it, knows no end. He is also one of those individuals who, if he had the authority to do so, would mandate that no individual can rise above the level of any other. Find and review his postings. I think you will come to the conclusion that he is a very bitter individual. I am guessing that he is one who apparently was kept out of ham radio by the cw requirement for some period of time. He is to be pitied actually.

Fewer hams don't need as much bandwidth. Nonsense? One ham doesn't need
any bandwidth. Nonsense? Dick, are you drunk again? If there were only
10,000 hams, we obviously wouldn't need as much bandwidth. If only one
ham existed, Why would he need any bandwidth? Who would he talk to?

I agree that this will affect match to the feeder, but I am also considering
the following:

Given that the Earth produces a boundary condition for the propogating wave
then the boundary condition for
the Electric field will be normal to or zero at the boundary and for
the magnetic field will be parallel to or zero at the boundary.

In the case of a perfectly conducting plane the current at the boundary is
maximum and the Voltage zero.
As you move vertically away from the surface of the plane the ratio of V/I

move from Zero at the boundary to the limiting value Quarter wave above the plane.

What I am suggesting is that the feed point and therefore the Voltage current pattern at that height above the earth plane can be nearer to that of a propogating wave constrained by the boundary condition outlined above.

I am suggesting that because the velocity factor at the skin of the conductor forming the radiating element does not permit the Voltage current pattern of the conductor to match geometrically the Voltage Current pattern in free space;
that elevating the feed point of the antenna a little above the plane of Earth the two patterns are aligned in a more satisfactory juxtaposition to provide a more efficient transfer from conducting element to free space.
With the added advantage that the requirement for a zero resistance at the point where the physical antenna meets the Earth is relaxed.

Understood, what I am suggesting is that the radiating element feed point is elevated away from the plane just a little to give some leeway in matching the freespace wave pattern resulting from the boundary conditions to the wave pattern resulting from the lower velocity factor of the radiating element of the AE.

A bit like using a large headed screw perhaps with washers in a big hole
when fixing front panels etc. in order to releive the drilling precison
(PCD) for the associated holes.

The fit is not exact, but a best fit.

That is an interesting point when considering horizon distance.
So you are saying take lambda /8 as the launch height
so what angle shall I use to calculate
the ray/earth intersection S = (lambda tan theta)/8 ?

> If you are interested

> lost the 3 dB boon.

So what we should be interested in is the rate of change of constructive
interfernce around that point with the change in height of the AE. We are
looking for the ideal point and then must make suitable compromise to match
that position at the feed point.
I suppose that it is a case of not putting the cart before the horse.
There is absolutly no way that a Ham can approach these launch conditions on
136 kHz
The way to 1 W ERP is via much more feed power and resignation to very low
efficiency. I suppose man has struggled along with X-Ray tubes at well below
2% efficiency for many years, so why not the same state of affairs for Hams
at 136 kHz :(
Obviously more radials will not produce sufficient efficiency at this very
long wavelength. nor I fear will my suggestion. Perhaps a small improvement

to efficiency of the system, but not a significant attack on distance for power.

But it leaves me a bit in the air if I read you correctly in that you are suggesting an optimum height for distance. From constructive interference between incident and reflected wave at the boundary.

Thank you Richard, your later part of this posting clarifies the issue considerably I make no apology for leaving in my earlier part of this posting as I work my way through what you have to say and the truth starts to dawn upon me.

I'd still like to try elevating the feed point to see what happens, this assumes sufficient radials of a practical length to provided the best loading current practicable.
A brighter torch at the right position above the mirror has got to be better than using a flat battery. ;)

517. Re: 6 M gamma dimentions

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-05 07:11:28 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3A5573B1.4385D217@bellatlantic.net>
Source record: 172886

First, .5 wavelength is WAY too long! 12" is a whole lot
closer. I'd recommend about 15" to start, with about 2"
clearance between the gamma tube and driven element.
You can always shorten the 15" dimension.

That answers your question. Now I'll add some more.
If reading about a different way to make a gamma is
not of interest, skip the long part. But do read the end of it.
Here's a long description of a really good and easy way
to make a gamma, once you understand it. It is easier
to make it as I'll describe with the gamma tube fixed
and no shorting strap to slide around.

Here's how I do it: I attach an S0239 to the center
point of the antenna so that the center pin is about 2" above the
driven element. I flatten the end of a piece of 3/8 tubing.
The tubing inner diameter size is just snug on the insulated
center conductor from RG8. I flatten about 1", with 1 blow
from a hammer). I cut the tubing to 15", flattened end to
unflattened end. I drill a hole thru the flattened ent to accept
a #6 screw. I solder a #6 brass screw into the center pin of
the S0239, after putting two nuts on the screw. I cut off the
head of the screw, and remove one of the nuts. I then attach
the tube to the brass screw with the brass nut and brass
lockwashers. I make an insulating strap to support the
tubing at about the 10" point. parallel to the driven element.
(I've seen these made out of plexiglass, but I use a high dielectric
plastic material.) Next, I cut a 20" piece of center conductor,
which I insert into the tube as far as it will go, after stripping about
1" of insulation off the outside (of the tube) end of the conductor.
I then pull it out slightly, to insure that he conductor does not touch
the tube. That completes initial gamma assembly.

To adjust, you sllide the stripped end of the conductor along the
driven element, starting at about 10" from the center point, until
you find best match. You then slide the conductor slowly out of
the tube while leaving the stripped end attached to the driven
element at the point of bets match found earlier, all the while looking
for the best match (lowest swr) There is some interaction between
the two adjustments. Once you have found the point of best
adjustment - lowest swr - check to see how much you can
shorten the wire. For example, let's assume the best point on the
driven element turns out to be 16" from the center, but you had to
pull the conductor 6" out of the tube. That means you can cut off
about 9" of the conductor. Remember, it started out with about

5" sticking out of the tube, so when you finished, you had about 11" of conductor sticking out of the tube. The big loop of extra wire needs to be eliminated. I usually cut the wire twice - I remove most of the extra wire with the first cut, re-verify that the thing is adjusted for best swr, then cut it to the final size and do the final adjustment.

Now, if the best feed point ends up closer to the center of the driven element than about 16", you can shorten the gamma tube by the amount of wire you pulled out of it. Lets say your best match was at 13", and you pulled 5" out of the gamma tube, leaving 10" of center conductor inside the tube at best match. You could then cut the tube to about 11", flattened end to unflattened end, so that your conductor did not have to loop backwards towards the center of the antenna.

That's the details. The net difference is a mechanically superior and easier to make match than the kind where the tube must be supported by both an insulating strap and a shorting strap. In the design I described, the tubing is fixed in place because it is attached to the SO239 center pin - you cannot slide the tubing around. In the other style design, you must slide the tubing around, as well as the shorting strap. Both designs require an insulated tubing support, but you don't have to make a shorting strap with the design I described. Both require two adjustments, but in this design you move only the coax. In the other, you must move the tube and the shorting strap - and sliding either one has the effect of "trying" to move the other so the mechanical manipulation can be a bit more difficult. The degree of difficulty of finding the correct adjustments is identical.

This is the end I referred to that you should read. When you find the point on the driven element where you get the best match. you are actually finding the point where the antenna impedance is about 50 ohms. However - to get current to that point, you need a conductor. (That conductor is the gamma tube, or if you use the design I mentioned, the center conductor stripped out of the RG8.) Great - we found the 50 ohm point somewhere out on the driven element - but we had to use a conductor to get the current out there. And a conductor adds inductance to the antenna system. We need to cancel out that inductance, and we do that with capacitance. Well, the gamma match consists of a tube with an insulated conductor inside of it. Two conductors in close proximity, insulated from one another, form a capacitor. So the gamma match assembly provides everything we need - the conductor to bring the current to the 50 ohm feedpoint, and the capacitor to cancel out

the inductance that that conductor introduced. The adjustments
you make are to do two things: find the 50 ohm point on
the driven element, and adjust the capacitance to counteract
the unavoidably added inductance.

Finally, if your antenna elements are cut to the wrong size,
a 50 ohm match will be hard/impossible. So make sure
the dimensions are correct! And if you cut stuff for greatest
gain, the match point will be harder to establish than if you
cut stuff for the broadest swr bandwidth.

Cec,

Some time in the dim and distant past I predicted that if
you superimposed a disk of chicken wire (or something) of
the same diameter on the top radials the resonant frequency
would fall from 3.95 MHz to a lower frequency but still well
inside the 80m band.

ie., the replacement would have a smaller electrical effect
than might at first be expected. I have now lost the
predicted resonant frequency.

Reg.

>
>Jim did write, or so it appears on my screen:
>"The conclusion is simply that Morse has new uses. It`s not "outmoded".
>That`s all."

Yep. And that's a true statement.

The mode was being discussed, not the test.
>
>Commerce, the military, and other agencies have abandoned Morse.

Except for a few specialized uses (like auto ID) that's true. The reason is simple: They don't want to pay radio operators. In fact, they are abandoning the whole concept of "radio operator". The Navy dropped that title recently.

>They
>communicate more than ever, but with other codes and voice.
>Today`s voice and data replace Morse.

Sure - because radio is just a tool to them. It's not an end in itself. They would abandon radio in a second if something else came along. They are rapidly abandoning analog voice modes. Who uses SSB besides, hams, cbs and some fishing boats? SSB was first described in 1915 and was on the air in 1923.

In fact, to a large extent both "radio" and "wire" communications are being abandoned. The revolution is powered by fiber optic communications.

> American Telephone & Telegraph
>Company no longer offers telegraph circuits to anybody, Armed Forces,
>included. Their name is phoney. It should really be just the AT Company.

Because they can't make money on them. If they could, they'd offer 'em in a second.

>The Western Union operator no longer occupies a corner down at the
>railroad depot. No Postal Telegraph messenger boys deliver "wires" on
>their bicycles.

Because a telegram would cost too much that way.

>Morse is no longer stylish,

That's simply a subjective opinion. All those hams who use it on the air every day don't agree.

> that is, Morse is outmoded.

Not the same thing at all. Can you actually say that Morse has absolutely no potential nor use in the "modern" world? There was already a post by a designer whose software causes computers to beep Morse error codes. Sounds pretty modern to me. Can you say that no disabled person will ever benefit from Morse as a communications method?

What you are doing is badmouthing the mode, not the test. Why?

The whole idea behind the radials, if I remember correctly, is to provide a low loss return path for the signal... so a spiral, if we ignore any coil effects, should be more efficient since it covers a greater area than straight radials...

Source record: 172894

My homebrew 13.5-ft 40M and 25-ft 80M bugcatchers get out fairly well on a 'ground' system consisting of the two 20-ft halves of a 40-ft extension ladder laid out side-by-each on two sawhorses in the back garden. They're noisy on rcve, but I can work the Js LP/SP from Zinzinnati on 40M, if I listen on a more-quiet antenna.

Other than having to adjust the feed taps and the top-hat tap on the loading-inductors, there seems to be no advantage in having the radiators in a particular position on the 'plane' from one end or the other to any place in-between. The 'ground' is my 'model' of my old pick-em-up truck.

With several chokes in the feedline, there is a substantial current on an ammeter connected between the 'plane' and the dirt-earth-ground below. Adding radials raises this current.

Corona is spectacular on a foggy evening ;-).

How many people know American Sign Language (ASL)? Probably only a few percent
of the hearing population at best. Does that mean it has no use? Of course not.

>> - Use of Morse for man-machine interface
>
>?
>Sorry, but I don't see ANY logic in how the use of Morse in either of those
>situations would be worthwhile.

Then you lack imagination and are simply badmouthing the mode.

> Which makes more sense, hitting several
>keys/buttons once to do something or hitting one multiple times?

Depends on the situation. Can you show that for all people, disabled or not,
for whom "hitting several keys/buttons once to do something" is easier than
"hitting one multiple times"? I don;t think so.

>Since these were your ideas could you please give an example of either or
>both to show what you mean?

Anything that uses electronics can be equipped to read out in Morse using a
simple piezo tone generator/speaker. Works in the dark, or when other parts of
the system have failed. Flashing LEDs do the same thing. Much simpler and more
universal than voice recognition/genrration.

Depending on the disability, Morse may be far more adaptable for some people
than other modes. A blind person with limited hearing may not be able to
understand speech or read, but the use of Morse could be very easy practical
for them.

But that would mean Morse is not "outmoded" or "obsolete". Not
electropolitically correct these days to find new uses for old things. Ending
is better than mending and all that.

Better set the boundary conditions:

1) "HF transceiver" means a rig capable of operation on more than one HF
amateur band. It must be tunable over a significant portion of the band and the
receiver and transmitter must track each other.

2) It has to actually have been built and be used to make contacts. Or have
existed and been used.

3) It can't be a copy of a commercially made product or basic design.

Jim P.

....thats interesting......I have often wondered what "modeling" would reveal. Now that you have modeled it, what are your thoughts?

Are the "traps" working as something other than traps?

In your modeling procedure, what would happen if you did the reverse of what you did...that is......if you did the 12M section first...then added 10 meters? (Bear in mind that I don't know much about "antenna modeling" on a computer.)

I tried building one several years ago, with the aid of a grid dip meter. About 5 miles worth of wire later, I gave up.

I just got confusing results....

I am currently wondering if one of these "Antenna Analyzer" devices would enable a person to build this antenna?

Note the smiley face. "Outmoded" means outclassed by another mode.
Get it? CW is certainly outclassed by PACTOR II. As far as class
goes, cost and equipment doesn't matter.

> Can a ham do PACTOR II and drive safely at the same time?

I certainly would not want to be on my motorcycle on the same
road as someone doing mobile CW. IMO, mobile CW is an accident
waiting to happen. I found it dangerous to play Morse practice
tapes while driving. While driving, distractions should be
kept at an absolute minimum.

Naturally, I left out a little - but important - detail. I hate it
when that happens. When you solder in the #6 screw -
or try to - you'll find it won't fit inside of the center pin
of the SO239. I forgot to mention that you need to
file down the threads of the screw for the length that
will be inside the center pin so that the screw fits
nicely inside the pin. Also, I should mention making a
bracket to mount the SO239. First, whatever bracket
you do make should be mounted using stainless steel
hardware. Stainless steel should be the only hardware
you use for U bolts and mounting screws with a beam.
To make the brack for mounting the SO239, make an
L out of a piece of aluminum. The aluminum should be
wide enough to easily accomodate a hole into which
you mount the SO239. The dimensions of the L should
be about 1 1/2" on the short piece and about 3 1/2"
on the long part. The short part should be bent into a
saddle - you can do that by placing the flat aluminum
over a pipe of the same outside dimension as the driven
element, and tapping it into shape with a hammer.
Finally, the bracket material should be stiff enough so
that it won't bend out of shape in handling. My local
hardware store carries just the right stuff - I think it
is 3/32 thick.

users

The difference from CB is slight. FCC staff has said to me that when
they scan the CB and Ham spectrum segments with an analyzer, they look
pretty much the same. That`s your quasi-official attitude. But, CB can
be used for commercial purposes, Ham Radio can`t.

Rules and regulations are different for the two services. They are meant
to be appropriate for the different intended uses.

I advocate spectrum continue to be allocated for non-commercial users.
The allocations should be enlarged as h-f spectrum falls from favor with
traditional commercial users. Hams need more spectrum for the growth in
numbers of non-commercial users.

Modes allowed should reflect uage, not dictate usage.

The U.S. Army Cavalry no longer rides horses. It consists of armored
divisions. They ride tanks. The U.S. Army Signal Corps no longer sends
Morse. It uses modern voice and data communications. Modern modes are
also more appropriate for amateur communications. But, since amateur
communications are hobbyist communications, CW should be allowed just
because an amateur likes to use it and it doesn`t hurt anybody or
anything. CW is not as effective as other modern modes. That`s the cause
of its demise. The Signal Corps no longer uses Morse, and no other
agency of the U.S. Government normally uses Morse, either. The Signal
Corps no longer needs an Amateur Radio Service as a ready pool of young
men already trained as Morse operators. Morse is obsolete.

Best regards, Richard Harrison, KB5WZI

Glad you reminded me, Reg. I had forgotten. The WX here has
warmed up and dried up to where outdoor experiments are fun
again. As I remember, I was disappointed in how little you
thought the frequency would change.

well a lot of it depends on how high your RVs antenna could be if your just talking mobile antenna you are talking only a mile or so if you can manage a 20 or 30 foot pole with a gain antenna on it you could get around 5 miles till you drop in a valley
good luck

Cecil your ignorance is showing again. When a CW station checks into the net it's *between* the SSB KWs, who are standing by to copy. An ordinary CW signal is no competetion with a KW SSB.
But then, if you admitted that, your goal of "one big band" with no subbands by mode would suffer wouldn't it?

I disagree, Dick. I can usually read CW between the natural pauses
in human speech. Did you realize that a SSB station emits almost
no power while the operator pauses between words?

Those wishing for a more conventional looking "top hat" should consider loading a bicycle or two up there on the roof. Where I live, people drive around all the time with bicycles mounted up there. No reason why you couldn't do it permanently. No whip required.

Just don't forget it is there when you get to the McDonald's drive-through.

Why would you say that? Mark's statement above is false. I gave
an example of why it is false. There are other examples like
commercial HF broadcast stations. In fact, to the best of my
knowledge, the ARS is the only service in the nation that still
requires Morse code for HF access.

He would have made the same choice as 99.8% of the rest of the
U.S. population. Like them, the odds of him needing Morse code
expertise are infinitesimal. Worrying about more probable
happenings is advisable.

Which brings up a question - have the widely-used modeling tools been
validated for non-conventional radiating structures? Back when I had
a real job, we tried to make SURE that a modeling system could be
trusted before placing bets on its result.

What are the validation limits? What kinds of structures are outside
the bounds for Mininec or NEC-2?

You learned the code *characters* first by memorizing them, which you
soon abandoned in favor of character then word sounds, if you became a
functioning CW operator beyond entry level.
No use in asserting that memory isn't involved in learning, everyone
who knows anything at all about learning knows that. Its the
assimilation of what is learned, when it gets integrated into the
individual's complete bank of knowledge that actual learning takes
place. The detailed early memory work of memorizing "facts" is just a
part of the whole.

I have an 80-meter off-center fed dipole that I want to trim to 40
meters and install in the attic.
The antenna is fed with ladder line, but I want to use coax to prevent
interference. Should I
completely replace the ladder line with coax? Or can I leave a length
of ladder line and run
RG-58 the rest of the way? Iï¿½ve seen diagrams using 300-ohm twin lead
and coax, so I wonder
if I can use the same principal with ladder line. Iï¿½ll need to know
what length of ladder line to
keep also. Iï¿½m assuming thereï¿½s a magic formula for this.

thanks.

No, don't say that. No one is saying that techs are "lowly", and
particularly those who are trying to upgrade. If there was such a thing
it' have to be those who continuilly criticize all other licensees
becase of the Morse code.
I believe some of these guys have never tried learning Morse code
because of an irrational fear of failing, similar to some people who
fear speaking in public.
It becomes a self-defeating handicap, all too real because of its
perceived existance. Why else would someone who truly wanted a HF ham
license deny it to himself over long periods of time? If he didn't
believe that he couldn't do it would he allow that sort of obstacle to
prevail? Most of us didn't. It's not rocket science.

Sorry Mario,

The lowest resistance, lowest inductance and lowest
impedance between two points occurs on a straight wire, ie,
a true radial.

A tight spiral of wire is an RF choke and a waste of good
copper.

So what is your point? Are you saying vanity and self esteem are bad things? Of course if someone gets exactly what you got at a lesser price it tends to piss you off. The parable of the vineyard aside.

Only the left want all to be equal without regard to effort or ability. The law has been changed, I accept it. The need to rub it in is really starting to upset me!

> practice?

Never, except when directed there when circumstances dictate. You should know this, if you've been involved in ham radio much. The Coast Guard routinely comes up on ham HF frequencies when boats (usually private craft) with ham radio declare emergencies via ham bands and the information is passed on to them. It has happened several times that I'm aware of in more recent years. If the boat station had problems using SSB, or conditions were just too weak to be heard by other SSB stations, then it would be entirely normal for him to call a SSB operator using CW. Happens routinely, but of course you're not familar with any of that, as far as you're concerned any station anywhere who doesn't employ latest techniques doesn't deserve to be rescued. We see.

>
> From history we find examples of rescue summoned by radio telegraph at
> sea which douibtless saved hundreds of lives.
>
> Radio watch on the CW distress frequency has ended. Why? There are
> better ways to call for help now.

There have been "better ways" for many decades now, but none that work better. I'd much rather have many thousands of very proficient, well trained,interested and *involved* CW ops monitoring 500 kc for my distress signal than to have a failure-prone sattelite system (a full year after it went into effect almost 100% of distress alarm signals were false alarms, which prompted most of the overworked deck officers who had been saddled with the additonal chore of adminisering theship's emergency signalling system, to just turn it off). That, coupled with the fact that all satellite emergency calls are said to be routed to single point, where a single person monitors them, and the calls do not identify the nature of the emergency nor who, nor what the sice of the vessel, persons aboard, nor details are passed on. The person just relays on the fact that there was a destress call - which can be assumed to be a false alarm untill proven otherwise.

Better than CW? I'm not surprised you'd say that. You just don't know any better.

To save lives, what works best should
> be used. Hoping someone is on-frequency and paying attention within
> radio range is inferior to calling on a satellite phone for help. Plain

But when you know the code well enough that is not a problem. You work SSB ect don't you? FM broadcast?
To a well worn cw op, there is really no difference. I can listen to code just as easy as voice. And I can transmit it with very little problem if my paddle is sitting on the seat next to me. But saying that , actually I don't do it too often. I'm usually on ssb yakking to all the my buddies and buddetts on 80/40m. I save the cw to when I'm stopped and I can kick back and relax. And be able to write calls down etc. But I could work mobile cw no problemo if I wanted to. But I can see where a slow-to medium speed dude/dudett might find it a hassle. I've got enough overhead built in to handle it. IE: 20 wpm seems like a crawl to me. Makes it much easier. To drive and work cw safely, you need it learned well enough almost to be a second languauge. Which to fast code op's it nearly is. Don't have to really think about what I'm receiving, I just receive it, just like someone in the back seat telling me how to drive...g MK

Hi Gary,

With this posting, I presume your interest lies in 136 KHz. Again, if
you will note the figures above, you should have no problems with far
ground reflections with the Brewster Angle running roughly between 5
and 10 degrees for poor conditions (not abysmal conditions tho').
These angles are to kill for in HF.

As for raising the feed point. This has nothing to do with the launch
angle because the entire structure is going to support the same
current distribution regardless of feed. (I will admit this is
another broad brush stroke again.) You may find some benefit in
regard to drive conditions, but losses (as always) remain in the same
places they did before the move (your only hope was to move a current
max away from a localized resistance).

You might try Roy's EZNEC in its free distribution form (you have no
complexities that would tax it and it would allow you to move your
feed and observe the consequences in RAM).

But I was talking to Richard who is a ham. Not BC station, not cber. If he "Richard" wants to work hf, as a ham, he must pass a 5 wpm test. Being as he said earlier that he knew code at 20 wpm, I don't see how this would be a problem. The ARS service is the only one I'm talking about. Unless maybe he wants to go out and buy a BC station. Or a cb. I guess we could discuss that at a later date. MK

What I want to know is how did you measure the power output? The margin
of error for most all ham instruments are more than that.

I've got a stack of 1930's QST's sitting next to me here. They are quite interesting. I like the july 35 issue with the mobile on the front. He's got some kind of whip antenna on the back of an old "ford"???, and is feeding it with twisted wire. H.P. Maxim was still the leader of the gang when this issue was printed. I've got a whole walkin closet full of old qst's. Some quite collectable. Fer instance I have not one, but two issues of the QST that shut down the ham bands for WW2. Had a yellow insert inside. I have a 55 issue that has a complete repro of the original QST in 1915. And while old, there is still tons of usuable info in them. MK

The one I saw was a real loose spiral. More of a maypole looking setup.
And more spiraled at the ends of the radials than at the base of the
antenna. MK

If you use only the handheld and its "rubber duck" antenna, your range will be limited. You will not be able to work another station directly (from your rig to theirs) much more than a mile or so. If the other station has a good antenna system, you may be able to work five miles or so.

A handheld with its rubber duck antenna is good inside the primary coverage ring of a repeater. That is, if there is a local repeater(s), with antenna(s) on a nice mountaintop, you should be able to hit the repeater for five or more miles away.

I use a handheld in one of my cars but I have an external antenna -- deck-mounted 1/4 wave whip -- and a small amplifier that takes the output from the handheld and runs 20 watts out. That 20 watts, plus

the 1/4-wave external whip gives me 10-15 miles of coverage, easily within range of several repeaters.

Another trick would be to use a mag mount 5/8 wave. You can get a dual-band mag mount for 2 and 450. Connect that to the handheld and you'll work up to 10 miles with the 5 watts.

Of course, all this depends heavily on terrain. If you are in the bottom of a valley, buried deep in the forest, don't expect to work anyone.

Rich you speak as a systems engineer, and clearly you have been successful as one. But systems engineers seem to always like things tied up in neat, tidy packages, with everything about the system functing exactly as designed. On ham radio that just won't work, and the widely divergent aspects of this service are in fact its strengths, and portray some of the weaknesses of the high tech modes.
The reason is simplicithy itself - no high tech mode is capable of intercommunicating with any other high tech mode, nor a low tdh mode for that matter. They are all totally incompapable. SSB and CW, on the other hand work very well together-if conditions on SSB fade out, merely switch to CW and complete the contact or quickly make arrangments to QSY to another band.
Happens all the time now, but won't when CW is banned. And make no mistake, your comments clearly indicate your mindset that since it is "outmoded" that it might as well disappear. For commercial and militahy use, it already has, save for ongoing niche applications. But for ham radio, nothing could be farther off base.

Dick

Why not? To me, listening to Morse is like listening to somebody talk.
Shall we ban talking while driving?

> IMO, mobile CW is an accident
> waiting to happen.

Show us some statistics.

>I found it dangerous to play Morse practice
> tapes while driving.

That's YOU. Not everybody else. What is wrong with live and let live?

Besides, one should not try to write while driving.

> While driving, distractions should be
> kept at an absolute minimum.

Then talking, eating, smoking, and playing the any sort of radio while driving should be banned. Harleys should definitely be banned because they make lots of noise and draw too many admiring glances.

Don't even get me started about the distracting properties of miniskirts.

What??? Being as they lowered the code tests, before too long I'll be a "SUPER" code op. Being as most of the newcomers will bypass the code, my spread over the average will increase. To these new guys, I'll be so blazing fast that they will bow down in humble admiration. Heck, it's already happening. When I go to a field day, I get people that will stop and just watch me for a while. They will look and stare, and walk off shaking their heads. I'm totally serious. It happens every year. Most muttering "how the hell does he do it". So I think your estimate of the future is quite wrong. MK

Dang!

Dig up the QST from 1969 or 1968 where DeMaw describes the 80 meter QRP rig built in a file card box. (That thing sort of started it all). I was one of the stations he worked (WA3IYC). Still have that card. He was pounding into EPA at midday using almost the same antenna. Amazing.

ehsjr wrote:
"Essentially, you are arguing for disbanding of the Amateur Radio Service, whether you realize it or not."

The "Amateur Radio Service" is a licensing vehicle for non-commercial users

The difference from CB is slight. FCC staff has said to me that when they scan the CB and Ham spectrum segments with an analyzer, they look pretty much the same. That`s your quasi-official attitude. But, CB can be used for commercial purposes, Ham Radio can`t.

Rules and regulations are different for the two services. They are meant to be appropriate for the different intended uses.

I advocate spectrum continue to be allocated for non-commercial users. The allocations should be enlarged as h-f spectrum falls from favor with traditional commercial users. Hams need more spectrum for the growth in numbers of non-commercial users.

Modes allowed should reflect uage, not dictate usage.

The U.S. Army Cavalry no longer rides horses. It consists of armored divisions. They ride tanks. The U.S. Army Signal Corps no longer sends Morse. It uses modern voice and data communications. Modern modes are also more appropriate for amateur communications. But, since amateur communications are hobbyist communications, CW should be allowed just because an amateur likes to use it and it doesn`t hurt anybody or anything. CW is not as effective as other modern modes. That`s the cause of its demise. The Signal Corps no longer uses Morse, and no other agency of the U.S. Government normally uses Morse, either. The Signal Corps no longer needs an Amateur Radio Service as a ready pool of young men already trained as Morse operators. Morse is obsolete.

Best regards, Richard Harrison, KB5WZI

Jason, you are so right! I've tried different methods and studied the
code for quite awhile but nothing has worked for me like Code Quick.

At field day I heard someone talking about "a LIGHT is lit" and I
instantly new the letter L. It took me a while to get around to it,
but I finally ordered the Code Quick system http://www.cq2k.com/
and I'm really learning the code now. I've been steadily progressing
along and now there are letters that I "just know" when I hear.

I whole heartedly reccommend the tapes/CD's + computer program.

When you say short radials I assume you mean 1/4 wl? So I guess you are saying that most of the increases you would see with a larger radial set are due to the overall gain at all angles? Makes sense to me. But to me, thats almost a contradiction in a way. If this if all true, which I don't doubt, why the many times larger increases in signal strength reported in real life as compared to a plot on eznec for example? Lets say that the reflection point is pretty much fixed due to far off ground conditions. If you run a plot on a 160 vertical, comparing 2 radials to 60 using average ground, maybe a 1.4 db increase. Not much. But then you hear reports of 10 db difference when comparing in real life. "Say for Toms example". Thats quite a difference from the theoretical. It's this difference that has me scratching my head. Either the difference in the theoretical gains are understated, or the far off field has more effect than realized. Being as with 1/4 wl radials, you are not effecting the far off ground conditions, that leads me to suspect the current theoretical gain numbers of adding more radials. What I really need to do is round up 60 radials worth of wire, and compare to 2 here at this QTH with my fairly good ground conditions. Thats the only way I'll really know the real difference for this area's ground conditions. Anything I read will be hearsay...g But even if I did that, I don't really know of an accurate way to measure my low angle performance other than just A/B comparisons. Kinda hard to do. I don't think just disconnecting 58 radials would totally cut the effect of having them layed out. I think they would slightly help even unhooked. So kind of hard to accurately test I would think other than totally getting rid of them. You don't really know the exact angle/angles being used for one thing. But overall, I tend to agree with your position on the remote distance reflection . We shouldn't really be effecting it much at all. Or I would think anyway. MK

Tom,
It's the same here, 28.00 - 29.7 Mhz. The
29.5 - 29.7 Mhz sub-band is for FM (and other
modes). No FM below 29.5 Mhz.

Right.

> > If the entire earth was

You have to define "entire earth" and "covered".
> > --
> > http://www.mindspring.com/~w6rca
>
> polar ice caps

That should be easy to prove.

Figure out how much water it would take to cover the planet to a given
depth. Then figure out how much water there is in the polar ice caps
and the atmosphere.

Also figure out how much rain could fall in 40 days and 40 nights.

My guess is there isn't near enough.

--

Phil Kane said it best. He said something on the order of the Bible not
being a science book nor a history book but the story of a people's
developing relationship to God.

If you want to pick the Bible apart on literal scientific grounds, you
need go no farther than the two contradictory creation stories in
Genesis. But the Book isn't meant to be taken literally.

Lots of evidence points to it being a breakthrough of sea-level
water into the Black Sea which at the time was fresh water and
300ft below sea level. They have uncovered an entire civilization
300ft below the present level of the Black Sea along with fresh
water shellfish. Makes a lot of sense to me. Someone looking at
the difference between the levels of the Mediterranean and the Black
Sea (lake) and knowing about earthquakes could have warned Noah
about what was inevitably coming.

But, you see, that's not true. Richard can use CB anytime he wants
to work HF. It doesn't matter if he's a ham or not. Lots of nocode
techs probably work HF as CBers. No test required. (Do you feel that
tug around your left ankle?)

Earth to Jim! That's exactly why PACTOR II outclasses CW. There
is no comparison. Note that I didn't compare them and say one is
"better" than the other. Only high class hams can afford PACTOR II. :-)
CW is the lower class ham's answer to digital RF. You have always said
that anyone could afford a CW rig.

> > As far as class
> > goes, cost and equipment doesn't matter.

High class things cost more. That's what makes them high class.
Is a Rolls Royce really any better than a Buick?

> To me, listening to Morse is like listening to somebody talk.
> Shall we ban talking while driving?

Some places are banning talking on a cell phone while driving. Call me
old-fashioned, I believe driving should receive someone's undivided
attention. If you rode a motorcycle, you would understand. When I see
a lady driver curling her eyelashes, I get the heck away from her.

However, a less than tight spiral of wire is a loading coil.
About a year ago there was a shortened dipole with end hats
made out of spirals. It appeared to be an OK design to me.
It offered some end-loading inductance along with end-to-end
capacitance. I've been thinking of trying it for a vertical.

How does one compute the design of a trap for an HF antenna?
(ie: # of turns, diameter of insulator, length of conductor around
the insulator, etc...) End result, if i have X amount of feet to
rig up a dipole, i need to determine the trap construction parameters.

I suspect this means feeding the G5RV "Marconi-style", which means shorting
the inner and outer coax conductors at the transmitter and feeding it as
an inverted-L against ground. Works pretty well.

It would be a two-step operation for me. I would model it using EZNEC
and then use the coil formula in The ARRL Handbook to wind the coil.
OK, maybe three steps. Fine tuning would, no doubt, be required. Roy,
does the free demo version of EZNEC handle series impedances/loads?

I have no self esteem. So I don't have to worry about what other people think. I'm gonna do what I'm gonna do no matter if others admire it or not. I do like the goofy look they get on their faces though. I've played the guitar for over 20 years too, and can kick butt fairly well, but I almost never play to other people. I'm a closet guitarist. If I sought others admiration at that , I'd probably be in a different line of work. :/ MK

Good point. There were some very large number of radio control hobbyists who had to pass 13wpm code tests back when just to be allowed to operate up the six meter band where one-way RC ops were permitted. They didn't whine about the code test, they just did what they had to do to get their birds up.

Cops and reporters would have absolutely no idea why the accident
occurred. Therefore, there would be no news report of such.

i have the T 6 tennadye log antenna that i need to sell
i got it last year and put it together and really never got to use it
pick up in mid tenn or i can ship

almost $500 if you got it new today with collins balun

$300 with collins balun plus shipping
will ship ups and i wouldnt have to tear it all apart

specs are 6 elements on a 12 foot boom 13 to 30 mhz
thanks
joe kane kf4toh

Hi Cecil,

I think the only limitation is in the number of segments (10 or 20?).

Which ones?

>I'm hoping that
>the Texas A&M library has a history of Morse code.

Most of them focus on the landwire telegraph rather than radio. Few
non-ham-radio books do a good job of recounting amateur radio history.

The term "radio history" to most historians is taken to mean "the history of
broadcasting". I enjoyed "Empire Of The Air: The Men Who Made Radio", but it's
about broadcasting. Ham radio is hardly mentioned at all.

Isn't that stretching the definition just a tad bit? A transceiver is simply a single piece of communications equipment that is capable of both transmitting and receiving. HF means the HF band. There is nothing in the definition that says the rig must even transmit and receive on the same bands, much less the same frequencies.

Actually, it was a take-away process. The federal government
expropriated the RF spectrum from the people who homesteaded
it. The RF spectrum should have belonged to the people who
discovered and developed it. Instead, the federal government
nationalized it, just like a socialist/communist state.

Source record: 172723

FM is allowed where most phone (AM/SSB) transmissions are. There is a limitation on how much deviation (bandwidth) the FM signal can use on some bands. Below about 29 mhz the following applies.

(f) The following standards and limitations apply to transmissions on the
frequencies specified in ï¿½97.305(c) of this Part.

(1) No angle-modulated emission may have a modulation index greater than 1 at the highest modulation frequency.

That means the deviation has to be very low (way under 5 khz) . You can find the rules to the exect band and limitations under the www.arrl.org web site.

In the ham bands above 50 mhz wider deviations than 5 khz can be used.

Your effort is laudable but of limited effectiveness. Any lightning
stroke that can travel miles through the air to get to your
tower/antenna isn't likely to be seriously deterred by the need to jump
the airgap on a switch or relay.
If you have the antenna switched directly to a good ground system you
will divert a major portion of the strike directly into ground, but your
tuner and other gear will be exposed to whatever portion of the strike
is attracted by its path to ground.
Bottom line: nothing works as well as unhooking and grounding the
antenna directly. That's what I do with my EDX2 that I use portable with
my camper when the rig is not in use.
I also move the antenna end away from the camper to protect it. If
lightning got into my motorhome it could easily cause damage that would
make a scortched tuner seem trivial.

Hi Dean--

>Almost all aspects of society are harried by wannabe factions today.
Unfortunately,
they are in charge of ham radio now.<

With all due respect, Dean, that sounds like whining bullshit. The fact is there are more licensed hams now than ever before, but we (and our kids) are opting to use our disposible income to buy computers, expensive software packags, digital cameras, flat-screen monitors, CD burners, and a host of new and interesting things that are fun.

Oh, we might turn on our fourty-year old SSB and FM technology so we can compare notes and solve our installation problems. Or, we may turn on our 70-year old technology and work a little CW because we enjoy it. Or we might exercise our instinct for armchair bloodsport by contesting.

But, face it, HF-style ham radio is about as exciting as a stale doughnut most days--and the hobby is booring itself into extinction! If manufacturers are leaving the ham fold in droves to produce more profitable commercial products, and if ham magazines are merging or shutting down for lack of revenue sources, it's because the "hobby" is in sunset mode and starved for cash--not because it's being over-run by idiots. Like ham radio, Hammond organs, Oldsmobiles, phonographs, and drive-in theaters still have their nostelgic supporters, but "mainstream" is no longer part of the lingo.

Not that wireless technology is stale! There's a zillion things happening, people everywhere are using it, and techno-hobbyists will play with it increasingly in their spare time. Why? Because it's new and exciting! But--hang onto your hat--it may not require a license to play--and it surely won't be done on SSB or CW. Instead, it will require a whole new set of skills--more complex ones--to deal with topics like spread spectrum TDM duplex at 2.4 GHz.

Think what the word might be like if you had to "earn a ticket" to run your pc? It's no secret you can talk world-wide, disrupt corporate web sites, and get into a whole lot of trouble with one of these desk-top suckers. But difficult licensure requirements?? Most people somehow manage to stay out of trouble and learn what they need to know without taking a test.

Ham radio is a little like collecting buggy whips. Not everyone wants 'em anymore, but the ones who do only defeat themselves when they fight over who the "real" buggy whippers are. In my view, the whole debate is is both silly and passe'.

Not knowing Morse on the HF ham bands is a disadvantage. It increases the
possibility of interference and decreases your options.

The analogy is useless. A much better one would be to compare Morse knowledge
to knowing how to drive a stick-shift vehicle today, when most vehicles are
equipped with automatic transmissions.
>
>> >Technology has made such tests no longer needed.
>>
>> Only if the ARS is to become a service where only type-accepted,

The amateur service has the most freedom of any service. No channels. Wide
choice of modes and bands. Power levels from milliwatts to kilowatts. Almost no
type acceptance. Authority to design, build, repair, align and operate all
types of radio gear.

All that freedom carries with it the responsibility to be knowledgeable about
the technology used.
>>

Nope - and the result is you are not authorized to drive a truck larger than a
pickup, let alone an 18 wheeler.

A full-privileges ham license is like a full-privileges driver's license.
Because of what it authorizes the holder to do, it should test for the
appropriate knowledge and skills.
>

That's exactly what happens when anyone puts a transmitter on the air. Part of the spectrum becomes unusable by others over a certain area. Using the radio spectrum is a special privilege because there are so many of us and so little spectrum.
>.

In the ham radio context of "saints and sinners", it's logical to consider those who break FCC rules as the "sinners".

Surf on over to qrz.com or arrl.org and look up the FCC enforcement logs. All sorts of enforcement actions for on-air violations like obscenity, deliberate interference, operation outside authorized privileges. Yet notice that NONE of the enforcement actions were against hams using Morse! It's almost always the voice modes that get the NALs.

To my knowledge, there has not been a single NAL issued to a ham for violations committed while using Morse on the ham bands for at least the past 10 years..

Yet it's the second most popular mode on amateur HF - just behind SSB and way ahead of all digital modes combined.

Look up the case of a two-time offender with the call WA6CNQ. The FCC recently stripped him of all amateur radio privileges EXCEPT HF/MF Morse! Why? Because even that guy hadn't committed any offenses using the mode, even though he does use it.

>
>For who? Them?

For anyone.

>What do you care unless you feel that it is taking away from
>your "glory" in being able to say that you are a marathoner?

The term "marathoner" would be redefined to a lesser standard. That's not a good thing.

What is wrong with pride in an accomplishment? What is wrong with having standards? If there's anyhting wrong with modern society, it's lack of standards.

> Would your
>ability to run 26 miles in x amount of time in any way be changed by raising
>or lowering the set distance?

Nope. That's not the point.

>If the distance was redefined as 200 miles I
>guess YOUR sense of accomplishment at being able to run 26 would be totally
>gone then right?

If the distance were lengthened I could no longer claim the title. If the distance is shortened the title means less.
>
>>Doesn't mean the folks who run 10 mile
>> "marathons" are evil or lazy. It DOES mean that the standards would be
>lowered.

And that's the simple fact of it.

What seems to really bother you and a few others is the existence of any standards or requirements for the ARS at all. It's not just the code test - it's the idea of any test, including theory tests, that might require any significant learning in order to pass.

I think most hams wouldn't oppose the removal of the code tests IF there were better written tests and some Morse-only HF subbands. But what you seem to want is a simple reduction of standards to nothing. Toss licenses at anybody who wants 'em. We've seen results from that sort of radio service, yet it's what you want to happen to the ARS.

That's what folks like me oppose.

>
Go to Reg Edwards' website and download his free software called "TRAPDIP".
It's a simple DOS-based program that lets you design 2 band trap dipoles. You
can play with the various parameters to see the effects.

You'll have to convert all of the dimensions to metric units, but that's not
much of a problem.

Fine-tuning will be required, but that's true of any simulation.

I don't have the website URL handy, but any search engine will find it easily.

By that logic, CW also outclasses Pactor2.

>There is no comparison.

Agreed.

>Note that I didn't compare them and say one is "better" than the other.

What does "outclass" mean to you, then?

> Only high class hams can afford PACTOR II. :-)

So class is determined by money but not accomplishment in your book. I see.

>CW is the lower class ham's answer to digital RF.

Uh huh. Nice weasel wording.

>You have always said that anyone could afford a CW rig.

No, I haven't. Produce the post. I have said that Morse gives the most results
for the money invested. That's a good thing. It levels the playing field.That's
another good thing.

What bothers many is that things like skill cannot be bought. They must be
(l)earned.
>
>> > As far as class
>> > goes, cost and equipment doesn't matter.
>>
>> Sure they do.
>
>High class things cost more.

Some do. Others cannot be bought at any price.

> That's what makes them high class.

Not in my book.

>Is a Rolls Royce really any better than a Buick?

A Rolls Royce Merlin is better than any Buick.
>
>> To me, listening to Morse is like listening to somebody talk.
>> Shall we ban talking while driving?
>
>Some places are banning talking on a cell phone while driving.

Because they have had tragic accidents blamed on the distraction of cellphones.

> Call me
>old-fashioned, I believe driving should receive someone's undivided
>attention.

Then you support the banning of talking, eating, smoking, and listening to any
sort of radio while driving.

>If you rode a motorcycle, you would understand.

What difference does that make?

> When I see
>a lady driver curling her eyelashes, I get the heck away from her.

Me too! That task requires looking away from the road. Mobile Morse doesn't.

I just don't hear SSB stations leaving long pauses between sylables. I find it curious that you can copy enough of the CW being sent to make out what is being said during the time the SSB op catches his breath. You sure you aren't reading it as some sort of multiplexing? Most SSB yakkers give out with the "Ah's" and "eh's' pretty liberally to fill up gaps in their transmissions. Like the BC boys, dead air time is a no-no. Your assertion is tenuous at best.

Big deal. RF is RF. And the main difference you see in monitoring AM BC and FM BC with a spectrum analyzer is that the FM's dance around at the modulating frequency. The significance of that statement is.....?

>That`s your quasi-official attitude. But, CB can
> be used for commercial purposes, Ham Radio can`t.

But somehow ham radio always shows up badly needed in emergency cases given the frailties of all those high tech modes the commercials have adopted.

> Morse is obsolete.
>

To you, to be sure. But then you don't do any CW, so that's about what your attitude should be expected to be. Should it ever occur that you desperately need it when it isn't available to you might rethink your position. And I'm well aware that is not likely, especially since you won't know how to use it. The last line of communications for you is one that you never learned.

It isn't the mode that gets busted. It is the operator. I would also venture to guess that most of those violators have passed the CW test. That kinda kills your observation thing. How many of those violators are no code techs? Someone said in another post that nc techs were the largest group of hams so they should be flooding the offices with complaints against them especially since they are worse operators because they don't know CW. For some reason that isn't happening.

It does? thanks for telling me what i feel. I didn't know that untill just
now. I could actually not care less about requirements for HF. I have no
interest in it at all. I never plan to upgrade no matter what the
requirements. My interest is uhf/vhf. I have a degree in electronics that

included 4 terms of communications theory as well as 3 years as commo in the Army so the tests aren't a problem at all. They just don't interest me. I don't enjoy contesting so there goes that draw. If I want to communicate long distances I will use something reliable and do it with someone I want to talk to instead of a random person that is going to give me a signal report and move on to the next guy.

I want nothing of the sort and posted a while back in another forum that i thought there should be CW only areas that require cw testing to operate on. As for the terrible state of CB i still don't understand everyones problem. From what i have heard on HF, cb is 100 times better everywhere i have ever turned one on. I am in Chicago and have never heard any problems on CB. Back home in a smaller town, cb was much friendlier than any of the ham bands.

Hi, Cecil-
No disrespect intended, but you couldn't get me to ride a motorcycle in traffic for all the tea in China! The odds are just too uneven if you ever tangle with an automobile. Heck, there are even a lot of tinny little cars sold that I wouldn't care to be in because they have all the crashworthiness of a cardboard carton! My brother, who is a volunteer EMT told me that some of his written procedures for dealing with crash victims vary by model, and for some of these sardine tins, they basically read "notify medical examiner". Ride a motorcycle? You gotta be kidding!
I can assure you that you would have been no less safe riding in traffic near me while I was operating mobile-in-motion CW. Face it- there are some risks in life. Technically, we should all drive with both hands on the wheel at all times, and in the right position, too. That is how they taught it way back when I went through driver's ed. in high school. Realistically, folks are going to have only one hand on the wheel quite often for brief intervals, for operating a car audio system or setting the heat or A/C, etc. If it is always done with skill and the right attitude, it can be done safely. Usually the bad accidents are happening because people get too much into dialing a cell phone or get into conversational areas that are too emotionally distracting.

Mobile CW is different because it can be done without the eyes leaving the road. You use your peripheral vision, you occasionally glance over at the radio, but it is really less distracting than popping a cassette or CD in or out. If you haven't actually done it yourself, I can see how you might not know this. My right hand rested on my leg to run the keyer paddles during transmit. It was maybe 4-6 inches away from the steering wheel. I was young and healthy and my reaction time was (and still is) excellent. I could get there *real* darn fast when I needed to. Not quite as good as two hands, but still a better situation than changing audio media, which is lawful and is not, to my knowledge, considered anyway near as dangerous as cell phone use. Again I stress- CW is a spoken language! And the CW conversations on the bands are a darn sight more civil and light-hearted than some of the voice exchanges I hear on the air! :o)
They haven't yet outlawed having conversations while driving.
By all means, do worry about the woman nearby in traffic applying makeup as she drives. That gives me the willies, too. But mobile CW ops, a rare breed, I might add, are no threat to you. Is that what is *really* bothering you? Sincerely & 73, David K3KY

Cecil-
While you can read CW underneath a big SSB or RTTY signal, it is distracting as hell and just sheer torture. It is a lot easier on the phone and RTTY boys who are riding over the little CW signal. Mixing these modes together in a band is my idea of a real bad time for a CW op. Abandoning present band plans that give CW some respite from the digital modes, or abandoning phone sub-bands is probably about the most effective way to kill off this still-thriving amateur mode, if that is your objective. 73, David K3KY

Source record: 172743

I came up with a plan for a ground plane built on a SO-239 panel mount jack. Radiator and radials cut at 6.1", radials bent down from level about thirty degrees. I made one up and did a quick test on a 10' pole with a CB SWR meter (all I have) and came up with a 1.5:1. Will this meter be accurate at these frequencies? Thanks for the previous replies and any help here.

It is obvious you haven't even seen an ARRL Handbook
or Antenna Book. Otherwise you'd know that they contain
no advertisements.

The texts may not have the academic rigor some would
like, but at least they show their algorithms, unlike a certain
web poser who keeps his proprietary.

Dick, this happens during SSB nets. Someone tries and tries to check into
the net using SSB and doesn't make it. He switches to CW for his checkin.
It is extremely obvious that there is a single CW signal in there. The
net control then asks for the CW station to check in, which he does. I
don't know why you are having so much trouble with this concept.

It is neither. The SSB net control operator simply directs the CW
operator to check in.

My objective was to check into a CA SSB net when they couldn't read
my SSB signal from AZ. Here's what I said in my original posting:

"I hear people checking into nets when they can't make it with
SSB and the weak CW signal is readable through the SSB KWs."

I don't know why you guys are having so much trouble with this
concept. From AZ, I could check into a CA net using CW when they
couldn't read my SSB signal. It worked like a charm.

Look closer, Jim. Many of those NALs were issued for jamming violations
by code-tested hams using CW (continuous waves). Human nature doesn't
change when someone uses Morse code. Morse code simply is not an appropriate
vehicle for supporting emotional outbursts. Spoken language is.

OK, I have a top loaded 80 meter vertical, overall height is about 20 feet, I used parts from a old hy-gain antenna, trashed the traps and just used the 80 meter loading coil near the top, the stinger I made up is adjustable so I can go from the CW portion to SSB with just a quick adjustment of the stinger. When the antenna is set for the part of the band I want to work, at the center frequency, the SWR is near 1.2:1 and is about 30khz wide at 2:1 without a tuner in line.

So instead of having 4 66 foot long radials (1/4 wave at 80mtrs) it would be better to have them cut to 20 feet long (height of the antenna)?

My back yard is 50 feet wide and right now I have them bending all over the place just to get them to fit. If the radials were 20 feet long I could have more of them.

With more (maybe 16) 20 foot radials would the bandwidth be better?

This maybe one of those try it and see.

In the broadest sense, yes. But in typical ham use, a "transceiver" is more
than just a transmitter and receiver in the same box. It's an integrated system
meant for the way hams operate. Plus there are lots of single-band designs.
Bandswitching designs are a lot tougher and rarer. That's the challenge!

Two more things:

- It doesn't all have to be in the same box.
- The same person has to be designer, builder and operator.

Those wishing for a more conventional looking "top hat" should consider loading a bicycle or two up there on the roof. Where I live, people drive around all the time with bicycles mounted up there. No reason why you couldn't do it permanently. No whip required.

Just don't forget it is there when you get to the McDonald's drive-through.

Which brings up a question - have the widely-used modeling tools been
validated for non-conventional radiating structures? Back when I had
a real job, we tried to make SURE that a modeling system could be
trusted before placing bets on its result.

What are the validation limits? What kinds of structures are outside
the bounds for Mininec or NEC-2?

You seem to using the wrong criterion for determining how "effective" your shortened antenna is. Your observation at the end of your post worries me:

> With more (maybe 16) 20 foot radials would the bandwidth be better?
>

You don't want better bandwidth, assuming you are talking vswr. Higher bandwidth indicates greater loss resistance and lower efficiency.

I think you would be MUCH better off with 16, 20' radials than four full length twisting all over the place (assuming the radials are laying right on the ground or shallowly buried.

The general rule(s) for radials on the ground are:

1. More is better, even if well short of a 1/4 wave.

2. On a shortened vertical, there is little to be gained by making the radials significantly longer than the physical length of the radiator. (especially if the increased length makes it less likely that you can run a large number of them)

If your ground losses are LOW (your radials are effective), then for the same antenna, your vswr bandwidth will be LESS. You will have a narrower bandwidth where the 2:1 vswr points are measured. This is a GOOD sign, not a bad sign. Having a "flat" vswr curve on a shortened vertical means you have a lossy system, either in the antenna, it's loading/matching, or the ground system. Electrically short verticals should ALWAYS have relatively poor vswr bandwidth, if they are operating efficiently.

I'm not asserting that radials have to be straight...that's a totally different point. What I am saying is that you should get as many radials down as possible, whatever their length and don't let length constrain the number. Longer radials can be non-straight, curve, bend, etc....although some would argue that they stop being effective if the bends are too radical, and amount to nothing more than a "shortened" radial in the first place!

So..back to the main point: forget using only four radials on the ground...that is way too few. Go with 16 shortened ones, and leave the four long ones you already have in the system, as they will only help and can't hurt.

(And expect the vswr bandwidth to be narrower than with just the four radials you started with. If it's not...something is not right...you have losses elsewhere in the system that you are not aware of.) Forget bandwidth as a measure of anything good about a shortened vertical. Good bandwidth is

always a BAD sign for this type of antenna.

I would disagree with but little in your response. It is quite obvious that we have different levels of respect and admiration for amateur radio. It is also obvious that we are not addressing the same train of thought.

The freebanders and no coders are the type of people who, having seen the parade want to join. They refuse; however, to wear the red conical hat with the tassel noting that they will wear their own favorite hat. Then they refuse to ride the identically configured motorcycle noting that they will stick with their dune buggy. No doubt they would complain bitterly because the power squadron refused to accept their sail boat entry in the annual power boat race.

These people always have an excuse why everyone else should do something their way. They have decided that everyone else is wrong even before they have become members of the process that they wish to enjoy. They want to participate and enjoy the process but they do not want to expend the effort on the common bond shared by the members.

These are the wannabes and they are indeed the true whiners.

Well I using that to say that it doesn't seem to be too lossey and
that the bandwidth is "reasonable" and that it won't cover the "whole
band with good SWR" so for a real short antenna it must be doing
fair.

>> With more (maybe 16) 20 foot radials would the bandwidth be better?
OK, I goofed with that term, Should have asked: 16 20 foot radials
(height of antenna) better than 4 1/4 wave radials.
>
>You don't want better bandwidth, assuming you are talking vswr. Higher

>the ground or shallowly buried.
Yes, the radials are laying on the ground
>The general rule(s) for radials on the ground are:
>

>
>2. On a shortened vertical, there is little to be gained by making the
>radials significantly longer than the physical length of the radiator.
>(especially if the increased length makes it less likely that you can run a
>large number of them)
Great! I'll try that, 20 foot radials are easier to roll up to get out
of the way to mow the lawn.
>If your ground losses are LOW (your radials are effective), then for the
>same antenna, your vswr bandwidth will be LESS. You will have a narrower
>bandwidth where the 2:1 vswr points are measured. This is a GOOD sign, not a

>a lossy system, either in the antenna, it's loading/matching, or the ground
>system. Electrically short verticals should ALWAYS have relatively poor vswr
>bandwidth, if they are operating efficiently.
OK I'll expect that the bandwidth will be tight.
Kind of figured with more radials one would get better bandwidth and
better efficiency. I really didn't expect the antenna to work because
it was so short, but when I worked EI6S and G4FIV (I know these guys
are EU 80 Meter superstations) from the west coast a few years ago, it
must be doing something.

>I'm not asserting that radials have to be straight...that's a totally
>different point. What I am saying is that you should get as many radials
>down as possible, whatever their length and don't let length constrain the
>number. Longer radials can be non-straight, curve, bend, etc....although

>73
Well thanks for the pointers, I'll give them a try, like I said, I
didn't expect the thing to work to begin with. Maybe later on down
the line I'll add another section of tubing to the vertical.

Being a "Libertarian" is the easiest thing in the world to be! With no values it is easy to follow and requires no thought or commitment to practice. But the word "Libertarian" sounds neat to describe a valueless way of life, and the other beauty is no one can attack your values, so you are always right and true to your principals. Sounds pretty spineless to me!

I am planning on doing some antenna work after the spring thaw. Due space restrictions on top of my 40' tower, I am planning on side mounting a Ringo Ranger at about the 30' level.

My question is, what should I consider as the minimum distance from the side of the tower? Fortunately, I am on the extreme edge of the area I wish to cover, so a shadow on the backside is not a problem. Is there an optimal distance at which the tower would become beneficial in the 'forward' direction?

I use 2 meters only as a local intercom with others interested in TTY and SSTV and currently am doing quite well with a copper pipe J-pole at 18', so I don't want to peel the paint on the neighbors house with RF or anything. I just don't want to make any blunders that could be avoided by a little forethought.

Thanks

Please send to all scanner enthusiasts, SWLers, and hams that you know in the US & Mexico:

==>ESCAPEES MAY HAVE STOLEN RADIOS; HAMS ASKED TO MONITOR

According to news reports, the seven Texas prison escapees still at large and now wanted in connection with the murder of Irving, Texas, police officer Aubrey Hawkins, KC5USI, also may have stolen radios from a Houston Radio Shack store. The radios are said to include Amateur Radio 2-meter H-Ts as well as Business Radio Service (programmed for 156.400 MHz) and Family Radio Service (462.5625-467.7125 MHz) radios.

Hams have been asked to monitor these bands and report any suspicious activity any hour of the day to the Huntsville Command Center, 936-437-6735, and to their local law enforcement agency. Police advise that anyone spotting these suspects not try to approach them but contact local authorities immediately.

More information on the escapees is at http://people.txucom.net/tdcj-iad/

Hi Gary,

I am responding to you through this posting because I can't find your response (I use several newsreaders and lost your response apparently).

If I recall, the jist of it was how to calibrate the noise spectrum of the PMT, and a question about its bandwidth.

First a source of information:
Photomultiplier Handbook, Burle Industries, Inc., Lancaster PA 17601-5688 (Formerly RCA PMT division)

In this there is a world of data presented for the noise characteristics of PMTs in general, and for several specific models (one of which I have had 10 years experience with).

From that ref, comes the specification of a flat noise spectrum from DC to -6 dB (current noise) 600 MHz. This is not your standard 6 dB/Octave rolloff as the frequency characteristic is established by transit times rather than RC (or RL) mechanisms. the rolloff is a plunge, but the DC to 100 MHZ is absolutely flat (to -0.1 dB with an eye straining interpolation). This spec is for their Type 931A PMT (with which I have long standing experience) which is a very good, but not exotic model. Typically costs around $300.

This says nothing of the absolute noise power (or noise voltage). That is simply because the output is extremely variable. The PMT is one of the greatest amplifiers ever built. When this model is pulsed (the power supply is pulsed on to measure a transient, the pulse of the power supply is to prevent catastrophic failure with runaway gain) it presents an amplification factor of 1,000,000,000. The lowest gain runs about 1,000 (PMT's operate linearly over a dynamic range 160 dB). This all sounds like fantasy for most Hams, especially when I trot out a spec like 20% quantum efficiency (at its absolute best - but I often worked at the 2% end of the spectrum). However, the eye, in comparison, is 50% quantum efficient. And the eye accomodates for

natural light conditions that vary by 80 db with a visual acuity range of 40 dB.

For Cecil (if you are reading this with your IEEE dictionary open), quantum efficiency is simply how many photons are generated for the number of photons striking the cathode). The transition (not transit) time from photon to electron is 1 picosecond.

So, to answer your question of how much noise, that is dependant upon the transfer equations for PMT gain against the source of illumination applied to the PMT. This particular handbook expends 15 pages in that discussion alone in "Appendix G: Statistical Theory of Noise in Photomultiplier Tubes."

This, of course is not the solution you are seeking insofar as finding a signal meter calibrator for the Ham shack. However it may serve as your gold standard for those models you design with the cost driven down to the Ham market (think in terms of an avalanche photodiode in place of the PMT).

For an example of my work with PMT's, Oximetery, and the world's most accurate Oxygen Sensor, visit my page at:

My experience with short, tuned loops is that they "want" to be tuned as a balanced radiator. In your case it appears that the shield should be connected to your chassis and ground. The variable capacitor should be floating above ground. The problem is how to couple this high impedance to the radio's 50 ohm unbalanced input. There are several ways to do it, but the simplest, once the preliminary adjustments are made, is to use a gamma feed.

Hi All!

I'm building a small receiving loop antenna for 160m using 20ft of RG58 coax
erected in a 5ft sq configuration.

I am trying to tune it using a large variable capacitor, it's one I've bought
for the tank cct of my home brew linear ...

Anyways, the capacitor is connected to the inner conductor of the coaxial loop with the coax
shield connected together as described in the book I have. I also have the 1 inch gap in the
shield at the top of the loop as detailed in the diagram.

Now the problem I have is that when I connect my MFJ SWR analyser to the antenna
and tuune for resonance on 1.84mhz I get a perfect 1:1 SWR by adjusting the capacitor however,
as soon as I let go of the capacitor / mfj analyser the SWR jumps up to 5:1 ??

Now I guess me holding these two units is causing some sort of capacitance either from the inner
conductor to the shield or to ground somehow, however I don't seem to be able to tune the loop
to resonance unless I am making a cct with my hands between the capacitor and the outer of
the coax.

Can someone please explain to me what is going on here and how it can be corrected ??

What I am trying to do is get the loop antenna to resonance on 1.84mhz and then use one of the
-30db nulls to block out strong signals from europe thus hopefully helping me hear the DX stations better.

Any advice, hints / tips etc will be much appreciated!

Cheers!

Hi Mike,

You might need to decouple the drive point from the drive line with a 1:1 current Balun. Of course there may another problem here with stray capacitance (which would mean a problem of a ground path) as you have already noted. It may also denote you need to feed with a capacitive divider (one of many feed configurations) since your body capacitance to ground seems to be a key component (if it in fact does not reveal the isolation problem that would be solved with the Balun).

I'm on a diet, so I have a wonderful supply of nice, heavy, straight-sided cans that I would like to build a "tomato" can antenna with. I can't find any information about how to do it. These cans are about 2-1/2" diameter and 4-3/4" tall. Do I need to take their tops and bottoms off? Do I solder all around the join? Where to I put the connection? What do I use for a base? Guy wires? Before you think I'm entirely crazy, I'm going to use them as a training aid in the "anything will work" department.

The problem is that you are looking for the wrong name- in the fifties, the big deal was the "beer-can" antenna. In those days the cans for the brewed nectar were steel, and could be soldered. Look back into the QST archives.

Bill-W4BSG (This call is 'vanity' now, but was earned by exam in the Customs house offices of the FCC, in Boston, in 1954 as an upgrade.)

RG6/U would probably be the best choice. You could go to RG11- but for the
expense you could install a good low noise preamp at the antenna and use RG59
and end up with a better C/N

that small? some diet!
>Do I need to take their tops and bottoms off?
All depends how you want your antenna "loaded" (empty the cans first?)

you will have a stronger, stiffer antenna if you keep at least the
base on.
>Do I solder all around the join?
nice sized tack points might do (solder at 3-4 even points for 1"),
but for the dimension you have above 2.5" diameter(?) that would be
nearly all around. If you have trouble with a too small iron (or gun)
try building a heat dam using toothpaste built up around (but not on)
the area you are working with the iron/gun.
>Where to I put the connection?
at the bottom

I am considering buying the MFJ-1788 Magnetic loop antenna that covers 40m-15m. Has anyone used this antenna? I am looking for any user feedback as to how well it works and ease of operation, especially tuning for receive.

I am concerned about the very small bandwidth of this antenna. I have heard the the bandwidth is just a few khz on 40 meters. I know you tune it by transmitting. So, how well does it work if you normally scan the band before transmitting? The manual says that you can tune for receive by manually listening for the capacitor motor sound, anyone tried this?

Thanks in advance

Nice thing about these cans is that the top 3/8" is smaller than the rest of the can. If I take the bottom off of the previous can, they will overlap probably 1/2". Is soldering good enough? Perhaps brazing would be better? What do you think that the minimum height should be, and which frequencies would work best. I'm thinking that a 50 watt 2-M won't work, that I'll need something with more "oomph".

Thanks for the information so far. I've got about 15 cans empty now and another 3-1/2 dozen to go. (current rate is 1 or 2 per day)

I would not even think of using RG-59. Use RG-6 it does not cost that much more than RG-59. Technically anything over 100 feet you should use RG-11. But since you state it is 120 feet I would not bother. Go with brands like Commscope, Belden, Stay away from RadioShack cable.

As Novice in the fifties I used a beer can vertical on 40m. My old man emptied
the cans for me and I soldered them together. A Coke bottle, (quart sized)
which was glass in those days, made a fine base insulator.

Almost any kind of string or rope will do for guys. Heavy monofilament fishing
line will work fine.

Leave the bottoms in except for the bottom one and solder them all the way
around. Tacking them will work until you try to erect it then one of the joints
will break and you start over.

Next you need a crystal-controlled Millen transmitter and a BC-342 receiver and
you're in business. (I still have both <g>).

Source record: 172631

Hi Mike , the trouble is that the cap should be floating (both sides above earth potential) I think so you need a length of insulated spindle to get your body capacity away. You didnt say how the RX is to be connected. The usual is a coupling loop. Setting it for min SWR does NOT tune it though! You would be better to put a small loop on your MFJ analyser and use it as a signal source to couple a signal into the RX loop. Then tune the loop to a peak on
the RX. The null is at right angles to the plane of the loop so depending where you are it may be difficult to null out Europe if say you want the States. The nulls are sharp and the peaks broad so there is something to be gained usually. Even quite small loops works quite well, I have used a 4 turn 14inch diam device on 160m and 80m mainly to get rig of TV tb. The signal will be 20dB or so down on a wire but the noise will be down as well. So hopefully the S/N on the required signal will be better. The depth of the null depends a lot on the balancing of the loop and not injecting signals into the loop from the coax feed to the RX. You may also need to detune any wire aerials nearby (i.e the TX wire) as they will inject noise and signals into the loop.

I use a 4 ft loop quite successfully for RX on 136kHz, and can hear most things.
Cheers de Alan

The overlapping joint scheme would work nicely. There is no question that brazing all the way around will be much stronger than soldering. Paint needs to be cleaned off the brazing area. You'll need a "serious" torch, oxy-acetylene or MAP gas type. You'll probably burn any zinc or tin plating off the steel can so painting should be considered else the antenna will rust pretty quickly. Keeping the thing straight is a bit of trick if it's long.

Whattaya mean by "oooph"?? There were plenty of 33-34 foot 40m Beer Can Verticals back when. 96 Slim-Fast cans required. Support it with a glass whiskey or wine bottle, feed it at the bottom and spread some radials around the base.

Mario Gelinas wrote:
"Can you tell me which coax (75 ohm) is the best for the uhf-vhf band?"

Loss for RG 59 is about 8 db per hundred feet at 470 MHz and increases to about 11 db at 800 MHz.

Loss for RG 11 at 470 MHz is about 6 db and increases to about 8.5 db at 800 MHz, per 100 ft. So, RG 11 is about 2 db better than RG 59 at these frequencies. For 120 feet, the loss difference is closer to 3db or about twice as much power loss in the smaller cable. A loss of 6 db means you`ve lost 3/4 of the power in the cable.

Loss for 120 feet is 20% greater than loss for 100 feet.

Best regards, Richard Harrison, KB5WZI

>does the free demo version of EZNEC handle series impedances/loads?
>--
The free version of EZNEC can be used to model a trap dipole. I've done both dipole and inverted vee configurations. The main limitation is that trying different parameters is very time consuming. And you have to figure out the trap parameters (L, C, and R) externally. This isn't a criticism of Roy's excellent software - it's just the price of using general purpose antenna simulation software for a specific task.

For a two-band trap dipole, it's hard to beat Reg Edwards' TRAPDIP. Simple and easy to use. Comparisons between results obtained with both EZNEC and TRAPDIP models shows good agreement. TRAPDIP tells how to wind the coils, and the value of trap capacitor needed, as part of the results.

Here's a sample. Took me about three minutes, including converting to metric and back to "English" units:

A 50 foot long trap dipole of #14 wire 30 feet up is to be designed. Desired resonant frequencies are 7.05 and 14.05 MHz. Coil forms 1-1/2" are available, and a "square" coil (length = diameter) winding is chosen.

TRAPDIP says the traps should consist of 21.3 turns of wire, and the trap capacitors will be 7.2 pF The traps should be about 17-1/2 feet from the feedpoint. Feedpoint impedance at resonance is about 49 ohms on 40 and 75 ohms on 20 - well under 2:1 SWR. Antenna efficiency over average ground will be about 89% on 40 and 96% on 20. (The model only takes into account losses in the ground, the traps, and the antenna wire, but the same is true of EZNEC). Of course all of this needs to be fine-tuned due to environmental variables, but it gives a good starting point.

I like coax-cable traps, and I use them, but for Steve's application coil-and-capacitor traps may be a better way to go. Coax traps' main advantages are ruggedness, cheapness of construction for medium power use and ease of weatherproofing. An attic antenna doesn't need weatherproofing and doesn't have to withstand wind, rain and ice. Coax traps are hard to trim to frequency.

Their biggest fault, however, is that you have almost no control over the LC ratio. With coil-and-capacitor traps, you have much more flexibility.

Mario Melendez, TI2DLL wrote:
"The whole idea behind radials is to provide a low loss return path for the signal."

Exactly. Covering a larger area improves contact, but the ideal path for the copper radial is straight away or perpendicular to the tower as that is the direct path the current needs to take for the least loss.

You also need to reach out if you can to a large cross-section of earth to get low resistance from the large number of parallel paths that a large cross-section implies.

> must be doing something.

Yep, it's the other way around usually. As you add more radials , the bandwidth will slowly shrink. Like he said, this is a good indicator that the radials are actually making a difference. The efficiency goes up, but the bandwidth shrinks. Most of the time you will see about rhe same effect in comparing a good loading coil to a lossy one. The higher the Q , the narrower the bandwidth you will see in the antenna it's used in. If you stick a lossy coil in it's place, the bandwidth gets wider. I think using the bandwidth is a reliable way to gauge the effectiveness of adding radials. As you add more, the bandwidth should shrink up until the point you are fairly well saturated with radials, and then the bandwidth reduction should taper off to where adding more radials make little difference. Once you get to that point, adding more a waste of time. The shorter the vertical the more critical the radials. A 20 ft 80m vertical is fairly short, so adding more should help a good bit if you have lossy soil. MK

Nah, the conductive resistance would be very low no matter how the cans are
bonded. The RF flows on the surface and cans have huge surface areas, both
solder and brazing rod materials are plenty conductive. Not an issue.

Not at all fussy. Simply attach the center conductor of the coax to the lowest
can and connect the braid to the radials and run the coax to the radio. The
input impedance should be somewhere in the R25+j? range which very roughly ought
to result in a 2:1 +/- swr at resonance with 50 ohm coax. Most xcvrs should be
able to handle it without any tuners. If the swr proves to be any higher an
autotuner or manual tuner will provide a 1:1 match.

Libertarianism is a political outgrowth of the philosophy of objectivism.
I know of no more objective philosophy. Ethically, it is pretty rigid.
No person is allowed to initiate the use of force or threat of force
against another. Under objectivism, all force is strictly for self
defense. It is a system of objective ethics, rather than subjective
morals that depend on what type religion one adopts.

Alright,

The best ground system is to copper coat the earth.

Ground radials are a way to make your patch of earth as copper-coated as possible and practical.

The more you have the better. If you can lay down a solid disk of copper, the bigger around it is the better. When it comes to approximating this with wires though, there are some considerations to the length vs the number of radials. If you have only a few radials (16, 32, whatever) you're not going to gain much by extending them out very far. Thus the "radials need not be longer than the antenna" rule of thumb. 0.1 wavelength is just as good as longer, because of the area covered.

If you have hundreds of radials, you can get good results by extending them out to 1/2 wavelength.

Spiraling ground radials won't do any good, because then the currents trying to make it back to the base of the antenna will have to spiral. (lossy)

73,
Dan

There are a gazillion ways to make radials. Maybe ten gazillion. I ran a chunk
of software written by Reg Edwards called "endfeed" and his program indicates
that your 40m FD vertical should be as follows for near-optimum radiation
efficiency:
>
Vertical should be 36 feet tall, 101 cans assuming a half inch overlap between
cans. Make it 36 feet plus or minus one can.
>
12 radials each 8 feet long. Not a critical dimension.
>
Radials can be made from Home Depot #14 insulated copper THHN "house wire". The
stranded type is easier to handle.
>
Radials should be more or less equally spaced in a circle on the ground around
the base of the antenna.
>
The ends of the the radials at the antenna all get soldered together and to the
coax braid. The center conductor of the coax gets attached to the antenna.
>
The far ends of the radials can be held down with wooden clothes pins driven
into the ground.
>
SWRs should be well under 2:1 between 7.000 and 7.300Mhz

Isolate the tuned loop. Make no connections to it. Couple it to the
receiver as with a magloop - using a smaller loop, 1/5th or 1/4 the
diameter of the main loop.

It is so. We are not even talking about the same thing. You could not possibly
have read with understanding what I wrote, as evidenced by your answer.
I am not talking about cross-mode cw on a phone net with a net control op.
I am talking about the chaos that would ensue if we dropped band plans and
sub-bands for phone.

>> Abandoning present band plans that give CW some respite from the
>> digital modes, or abandoning phone sub-bands is probably about the
>> most effective way to kill off this still-thriving amateur mode, if that is
>> your objective. 73, David K3KY
>
> My objective was to check into a CA SSB net when they couldn't read
> my SSB signal from AZ. Here's what I said in my original posting:

My objective is to speak up for the *amateur radio* CW mode when I read
others maligning it. Labeling CW obsolete might be either true or false
depending upon context. In the amateur radio context, CW is undeniably
alive and well, yet some folks feel the need to pronounce it dead.

David Sinclair wrote:
> If you haven't actually done it yourself,
> I can see how you might not know this.

I've tried it. That's why I know how dangerous it is.

> Again I stress- CW is a spoken language!

Which is a false statement. From Webster's:
"spoken - delivered by word of mouth: ORAL"

Cecil, I have looked foreward to reading your posts and have found them
interesting. Sometimes I also shared your viewpoint. This thread has
been a sometimes funny, sometimes distressing no code/pro code bash
that got started by the incorrect association of a tech class ham with the
Wakefield, MA killings. Sadly, it appears you are being quite inflexible,
even defensive, and are more interested in bludgeoning the group with
your own viewpoint than in truly listening and interacting with others in an

unfolding dialectic. (see Webster)
If it makes you feel any better, I will cede you and Noah Webster a small, technical victory over the trifling point that CW isn't an *oral* spoken language, strictly speaking. OK. But in your heart of hearts, you know that it is a language. And it is indeed auditory, as it is used in radio. :o) So it is 'spoken' with the hands, yet heard with the ears and processed in the brain. Just like speech. Wowza! Hey, its sorta like low data rate speech- get it? I could also whistle morse code for you, but that would probably still not convince you. How about if I vocalize it for you using my larynx- am I getting any warmer? No? How 'bout if I record my voice and then play it back for you- am I really 'speaking'? I would say no- I am sending information to you using my hand. Oh well, this is a 'technical' hobby, after all... :o)

You may 'know' that your mobile CW operations were dangerous. Perhaps they were. I certainly agree with listeningly alertly to our feelings and honoring them. You probably did the right thing by stopping, then.
I 'know' with equal certainty that my mobile CW operations were not dangerous. I have the advantage of having been there. You were not.
I'm a pretty cautious person, I might add. Pretty conservative. Real careful. My friends tease me about that from time to time. Now, I actually have done a few questionable things while driving, in my time, but I can assure you that mobile-in-motion CW was *not* one of them. I am no more qualified to state opinions about whether or not you are safe while using your shop tools than are aliens from outer space. I have never observed you do that. Some people are safe, some people saw their fingers off. Are you really going to be so rigid in this discussion that you insist that any and all activities that remove hands from the wheel or eyes from the road are "unsafe"? While you could make a technical case for that, the billions of safe road miles racked up by motorists belies that claim, and are a testimony to their collective skill in executing the task. While many activities do pose a *potential* danger, it really all depends on whether the driver has internalized the 'prime directive' of driving: driving comes first, always- everything else is secondary. There is something so secuctive, so captivating about mobile cell phone use that some folks completely forget their driving. I can see that. It takes a while to dial a number and you pretty much have to look. Folks discuss just about anything on cell phones- can you picture a driver's emotional state after having just heard that a child has been injured or they are getting laid off or fired or their love interest just broke up with them? Ham CW chats are pretty bland by comparison.
I don't intend to get 'tarred with the same brush' over my mobile CW operating and compared with far more risky behaviors just because in your mind they are all lumped together and represent a potential danger to you as a motorcyclist. Again, I must express my respect of you for your transport bravery. I think it is too much of a risk personally, and would not ride a motorcycle even if offered large sums of money to do so. I just value my life too much. To each his own. Like most things in life, it is a question of degree, and I found mobile CW to be an acceptably safe and enjoyable activity. I heartily recommend it to any

ham who is an experienced driver and CW operator and in good physical condition. For these folks, it is not much of a reach, and it is truly one of the joys of ham radio. 73, David K3KY

Hi Dave!

Thanks for the info.
I am reading this design from an antenna book I have purchased,
The author details that the feed coax from the RX be connected directly to
the loop,
that is inner to inner and outer to outer, there is no mention of any type of
matching
circuit in the article ?

I will now go away and read up on gamma matching !

Cheers!

MikeT ...

> 73's
> Richard Clark, KB7QHC

Hi Richard!

Thanks for the info.
According to the article I am getting the design from, the author details
that the
50ohm feed coax just be connected directly to the loop, that is inner to
inner
and outer to outer, there is no mention or even detail in the diagram of any
type
of matching component, just a direct connection.

A current balun makes sense though, I'll read up on how to make one and then
have
another go at tuning the loop.

Cheers!

Hi Alan,

Thanks for the info.

The rx is connected directly to the loop using the same RG58 coax, that is inner to inner
and outer to outer, exactly as detailed in the authors design and indeed diagram.

I've tried the insulated spindle, it does get rid of the problem of the stray capacitance
however the SWR will not drop below 5:1 when checked with the MFJ VSWR analyser.

It looks like I need to work on isolating this loop completely from the ground system, it's abviously
getting a connection back to ground via the RX which is connected to the shack earth system which in turn
connects to the earth radial system outside.

Another article I have read talks of having too much capacitance in cheap RG58 coax making the antenna impossible
to tune ?? I am now also wondering if this is a factor I had not thought of ??

Back to the drawing board I guess :)

I've had a few other replies and things to try so I have plently to experiment with.

Cheers!

MikeT ...

Hi Reg!

Will a loop of this sort of design still have the two deep nulls that I
am after ?

The book I have does talk of this type of loop antenna, but says nothing
of the deep
nulls that the other single loop design talks of.

>brain. Just like speech.

I go away for months, and this old chestnut rears its head again.

Morse is an encoding of the roman alphabet. The words of a language
can be *spelled* using an alphabetic encoding, but it is the words, and
their syntax and grammar that comprise language, not the alphabetic
encoding used to represent their spelling. Example, here is another
encoding of the roman alphabet:

ABCDEFGHIJKLMNOPQRSTUVWXYZ

Now is that a language? Of course not. Neither is the Morse encoding
of that same alphabet. A language has words, syntax, and grammar,
an alphabet does not.

When we pronounce a spoken language, we don't just sound out letters,
we pronounce the phonemes for that language. There are 43 of them
for English, and they aren't the same as the alphabet (which often gives
foreigners trying to learn English fits). When we send English text using
Morse alphabetic encodings, we do not generate the phonemes of the
spoken language either.

Morse is neither a written nor spoken language, by any stretch of the
meaning of language. It is an encoding of the roman alphabet, exactly
as are ASCII, Baudot, and a number of other representations of the
roman alphabet used to convey message texts in some actual language
such as English.

That's the pot calling the kettle black, don't you think? Here's what I
wrote three postings ago and what I have been arguing about and defending
in the subsequent postings.

"I hear people checking into nets when they can't make it with SSB
and the weak CW signal is readable through the SSB KWs."

Dick came back and said immediately following that statement,
"Cecil your ignorance is showing again." I defended my above statement
because I accomplished such regularly when I lived in AZ.

> Sadly, it appears you are being quite inflexible,

Refusing to crucify the English language by insisting words mean
what words mean is inflexible????? How about accuracy? Oops, I forgot.
It depends on what the definition of "is" is. :-)

> If it makes you feel any better, I will cede you and Noah Webster a small,
> technical victory over the trifling point that CW isn't an *oral* spoken
> language, strictly speaking.

Actually, the statement was 100% incorrect. CW is not oral and Morse code
is not a language. It is a coding system for a language, like ASCII is.
You can say the Morse short forms make it a language, but those short
forms can just as easily be used with ASCII or any other digital coding
scheme. If you can use PACTOR instead of Morse and get the identical
meanings across using the identical characters, then Morse is not a
language. If I can use an SCS PTC2e for Morse in the same manner that

I use it for RTTY, then Morse is not a language.

> OK. But in your heart of hearts, you know that it is a language.

Nope, it's not. My heart doesn't matter. A thing is what it is no matter how you or I feel about it.

Your language is what it is. Morse is a coding method overlaid over that underlying language and works as long as one knows the correspondence between the coding characters and the alphabet of whatever language is being used. In the absence of any real language, including words and definitions of concepts, coding would be nearly useless, like the grunts of a cave man. Helen Keller is a good example. Until she made the mental connection between the hand coded method of communications and the concepts of the language she remembered as a very young child, those hand coded symbols were meaningless to her.

> I could also whistle morse code for you, but that would probably
> still not convince you.

I can whistle ASCII for you at four baud, but that doesn't make ASCII a language. :-) Morse and ASCII are what they are - coding systems. The fact that Morse is a manual/aural coding system doesn't detract in the least from its functionality and usefulness.

769. Travelling wave HF vertical help ?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-07 15:14:51 UTC
From: Greg Webb <greg@eon.net.au>
Message-ID: <3A5887EB.332CF8B8@eon.net.au>
Source record: 172643

Hi Folks !

I am after instructions on how to build or buy that excellent HF antenna

the CC CTW travelling wave vertical for 1.8-30MHz it is 33 feet long
with a magical matching section on the bottom (this bit is the holy
grail
of antennas or so it seems..some say a transmatch, some say how can this

thing work, it is almost an artificial dummy load). If memory serves it
was
quoted as being flat SWR across the bands with no ATU needed.

Do they still exist ??

Cheers and 73's,
Greg VK6JGW

Hello Mac,

Looking at my Handbooks, here's what I see:

The Handbooks devote about the same space to tubes (about 35 pages) from the earliest one I have (1948) to about 1970. The tubes presented are only a small sample of those made at any time, and the characteristics shown are very limited.
During the late '50s and early '60s, the number of tube types manufactured grew tremendously, but the Handbook space devoted to them did not, so the percentage represented dropped. Just compare the size of the various RCA receiving tube manuals to get an idea! Many of the tubes, though, were not of primary interest to the ham, or were variations on older types (different pinout, different heater voltage, etc.) For example, the 6GE5 (used in many low-end Heathkits like the monoband SSB rigs and the HW-16) is just a 6DQ6B in a single-ended Compactron bottle.

I have to disagree in part. It all depends on what part of radio we're talking
about. Things like basic DC theory haven't changed. There's more to know
because there are more options, though.

What HAS changed is that folks can get their hands on very sophisticated
technology at relatively low prices, and that tends to chnage perceptions.
>

>made gear.

Agreed. Notice also that the old IRE stuff was often intentionally or
accidentally difficult to understand even for the professionals. Often the
theory was way ahead of the technology available.

Most important, by about 1925 (probably earlier) the average ham station was not "state of the art" as defined by the pros. Just wasn't practical for most hams. Ham radio made its contributions on the technical side in specialized areas (the single signal crystal filter and the noise blanker) and by serving as a first step for many people in all walks of life (young ham decides to go to engineering school because ham radio showed the possibilities of engineering).
>
>No longer true, except *maybe* at the most elementary levels. Even the QRP

The good ones are, anyway. But even a simple two-tube regenerative receiver requires a lot of understanding of basic principles if it is to be any good.

I agree - but at the same time, the math and science skills of much of the US population lag far behind what's needed.

>The ARRL Handbook these days recognizes this,
>and
>tries to get a balance between science and practice that is optimum for
>radio
>amateurs and students, but also challenges the mind in new directions.

I've seen many of the Handbooks from 1938 to the present. All of them have weak and strong points. The projects in many of them aren't "state of the art" by any means - for example, the DCS-500 receiver that was the most complex design presented 40 years ago was not comparable to, say, a 75S1. Several years later, the HB-67 receiver design was no match for a round-emblem 75S3B. They weren't meant to be - they were examples of what a ham could build in a typical basement shop with a reasonable set of tools and test gear.

>matters
>that pertain to amateur radio.

Agreed! Modeling antennas, for example, sure beats endless cut and try, seeking a solution that may not exist. But modeling is only the first step - the antenna has to actually get put up to do any good. And a modeling program does not automatically instill an understanding of antennas in the user. It can, however, inspire the user to learn and understand more.
>
>And if we are going to move beyond the mythology and folklore and snake-oil
>that
>has pervaded amateur radio for many decades, we have get up to date in our
>skills
>and attitudes.

I have almost always found that the information presented in ARRL publications was accurate and devoid of mythology, folklore and snake-oil. Not so with some other publications!

The trouble, as I see it, is that hams today need more background today than in years past, but the societal trends push the other way. That puts hams and their publishers in the uncomfortable position of swimming against the tide.

One thing I have seen becoming more prevalent is the tendency to seek quick simple answers to complex questions. Sometimes the oversimplified snake-oil answer is given because the questioner will not sit still for a complete answer. (Or the answerer thinks that way!)

This discussion is very apparent in antenna situations because most hams still have to do a little "engineering" of antenna installations. Even a manufactured antenna usually has to be selected, assembled and installed, and the results obtained depend in large part on how those steps are done.

How do we push things in the right direction?

Can't speak for the MFJ in particular, but I've worked several happy hams
who were using that type of loop.... very NARROW bandwidth as you describe.
The hams I've met who like them, are in a bad situation when it comes to
antennas.... they're looking for ANYTHING that'll get them on the air from
an apartment or condo.... usually several floors up... in that instance, the
loops seem to be the only way out.... and a HUGE compromise in antenna.

I just bought one of these dipoles from HRO in Atlanta. Due to space limits at my qth I need the smaller length of this Dipole ant. However it came with no Instructions for the placement of the traps. I called HRO and they just sadi that all of the others had no instructions as well. I also tried to reach the Manufacter but with no luck. They don't seem to have a listed phone and no answer to three letters.
Any Help would be helpfull.

36 feet? OK, I've got a lot of "Slim Fast" to consume - should be able to get it done by field day. If one was buying "Slim Fast" just to make an antenna, just the cost of the cans alone would be $75 - a person could almost buy a ready-made antenna for that price (but it wouldn't be as fun) I'll be back when I finally get enough cans to put this thing together. No wonder they were so popular when made out of beer cans ;-)

Yes Mike. ALL small simple loops have nulls broadside-on to the plane
of the loop. The greater the isolation of the loop from feedline and
ground connection the sharper the null.

Using 2 or 3 turns allows a tuning capacitor of only 1/4 or 1/9 the
size. No need for a screened loop. Just use hefty wire. It will be
more efficient and more simple to construct.

For design of multi-turn receiving loops download in a few seconds
program RJELOOP3 from website below.

i think what he is refering to is that as of jan 1 the arrl has allowed VEs
to increase there testing fees to $10 up from the $6.75 or what ever it was
the last time i tested to cover there costs and stuff your NOT buying a
license at all just helping the VEs with the costs

If you have hundreds of radials you will get very high efficiency with short radials. To extend them out to 1/2-wave will increase signal strength by a insignificant amount. You can't get any more than 100 % efficiency with any length of any number of radials. A waste of copper and digging effort. Money would be better spent on a bigger PA.

How about 3/4" hardline? He might be able to get that long a length of it for free, or almost free, from his local TV Cable System. There is a lot of it that is no longer being used - as the systems convert to fiber.

Bill you are correct however thet may be overkill, same with RG-11. Yes yes I know the difference between 100 feet and 120 feet, but the guy is not building an EME setup here. Keep it simple and lowcost.While you can get hardline for nothing, can he core it? I don't know his particular setup or expertise so I am not sure. I would just go with RG-6 yes double shielded is delightful all the new stuff is quad shielded so if he wants to get that, more power to him. RG-6 with a preamp at antenna. Not a radio shack preamp, get a Blonder and Tongue amp if you can. That way you put the amp in once and hopefully that is all.

I would agree, even the worst UHF preamp would yield a lot of improvement
at the higher UHF channels given the cable losses.

Hmmm. Right is purely real. Left is purely real. Left and right are opposites. 90 degrees away from right and left, therefore, is purely imaginary.

Now it all makes sense.

Dave, K3BHJ wrote:
"I have some mildly-libertarian views, but don`t think municipal garbage collection is an overly-intrusive-government action."

That`s a good example of pragmatism in the experience of my community. Reformers have gotten privatization several times with worse results every time, so far.

In my book, libertarianism is advocacy of free will and freedom of choice. I see practical problems with citizens getting fee relief for hiring a private removal service for their own trash, while the municipal service continues in competition. But, the right to private garbage removal should not be abridged.

I think Morse should be allowed on the ham bands, but expect a steady decline in its use. Many avid ham CW operators came from the ranks of former military Morse operators. This is ending and with no more supply from the military, Morse code operation will dwindle.

Best regards, Richard Harrison, KB5WZI

Hi Jim,

Your mention of the handbook containing tubes of interest to hams is right on, but back in the 60's I was more concerned with finding out what a particular military tube was (like the 6201). Most of my tube books were crossguides (cheapest solution) which often lead right back to the handbook's selections. Having just the tube base chart was worth it.

You mention the explosion of tube types in the 50's and 60's. Yes, most of them for TV's with combination functions. Some compactrons (if I recall the term) contained three tubes in one glass envelope. Sort of bottled circuits instead of integrated circuits...
BC's - IC's

The TV tube industry strove to drive production costs down to the point where they could build the equivalent to the radio's all-american 5 (5 tube receivers). Solid state moved faster. There was also a time when some business analyst crowed no one could undercut the price of cheap hong kong gear watches - a couple of years later they were dumped into the trashbin when the two component watch ('tronics - display with a dab of epoxy to seal everything) took over.

Well, you might just as well mark your calander so you can come back in
a few months and replay it all over again, cause "Morse as a Language"
is not going away. It's here to stay, for longer than anyone reading
this. And it has been so for longer than any of us has been around.

Any Morse operator who has learned and practiced the skill *to fluency*
knows full well that it IS a language, and in fact it meets all the
dictionary criteria for definition as one.
It is only those who never learned to hear words as CW sounds who
continually harp on the incorrect assertion that it is nothing more than
an encoding of an alphabet. That's because for them that's all it ever
is. When one must decode every dit and dah to letters which then must be
strung together as words, it is not a language for them, for sure. But
they certainly should be cognizant of the fact that their personal
experience is not all-encompassing of the human experience on this
subject, just the same as in other subjects. Just because I've read a
little on nuclear science doesn't mean that I'm an authority on the
subject. Just because they have worked CW doesn't mean that they are
fluent to the level of language in it.
I suspect that they really are that smart. That means that an Agenda is
in progress, that of further attempting to destroy radiotelegraphy in

ham radio.

The conclusion seems inescapable. Destroy all attractive attributes and there can be no reason to retain it.

> because there are more options, though.

The thing that I see missing is an indepth comprehension and comfort-zone of *basic, fundamental principles*. I am convinced that this is much more important than any of the intuitive and arm-waving methods that we use to try to get a handle on higher levels of things. By that I mean the ability to strip a question or a problem down to its most basic and simple ideas, rather than trying to leapfrog to (and getting confused at) higher levels. As I get older and no longer struggling to earn a Company engineer's pay check I find myself focusing on the beginning principles and mathematics (from the ground up) of various topics that I am interested in.

Maxwell's equations are a good example. They are about as fundamental and trustworthy as we can get in the field of engineering-type electromagnetics applications. Textbooks take these four equations and explain zillions of applications (at the engineering level) in ways that we can trust. But this is not an *easy* process. I keep struggling with it.

About DC theory. I have recently been learning about DC biasing and feedback methods in integrated circuit opamp design, just as general interest. There are a lot of nifty ideas there that stretch our understanding of DC design.

> Notice also that the old IRE stuff was often intentionally or
> accidentally difficult to understand even for the professionals.

The real problem here is the *art* of explaining topics in a clear and straightforward way. Many very smart people do not know how to do that. They do not communicate well. It is not an intentional thing, nearly always. On the other hand, people at the cutting edge of some subject talk to their peers and really do not want to communicate with those of us who are at the novice level. We should not be too critical. Einstein wrote a nice article on Relativity for Scientific American.

> (young ham decides to go
> to engineering school because ham radio showed the possibilities of
> engineering).

A-OK on that, big time. One outstanding example in science is Paul Horowitz, who wrote nifty articles for QST while in High School. Also engineer Terman and very many others.

> But even a simple two-tube regenerative receiver
> requires a lot of understanding of basic principles if it is to be any good.

There is a lot to learn about these "simple" receivers. Ask Charles Kitchin, N1TEV.

> math and science skills of much of the US
> population lag far behind what's needed.

Educators are busting their buns to deal with this. We radio amateurs can help, by example and by encouragement.

Snip the rest. I am sure we are on the same channel here.

So, Reg, where is the breakover point, the spot where diminishing returns is reached where one can have a number of radials and wishes to, or must, keep them short? How long should they be for "reasonable" efficiency when, say, 8 to 12 are used? Maybe we should say, what portion of a wavelength should they be as a minimum?
I've read for years, from a number of sources, that several short rsdials are as good as fewer a 1/4 wavelength long.
This could turn out to be a quite important factor in amateur radio vertical antenna installations as more hams are forced to smaller real estate plots.

Don't waste the money. That has been done in the past - and, in many instances, it has been uncovered. The problem then is that the FCC wants all the folks who tested before those 'questionable' VEs to take the exam again - this time in front of an FCC examiner. Failure to do so results in revocation of the license (and you don't get the money back!). Should this happen in my city (Rochester, NY), that means a trip to the FCC in Buffalo - 60 miles away. In many cases, someone is going to have to travel a lot further. Not pleasant.

73 from Rochester, NY

Greg,
I haven't heard about this 'CC CTW' antenna, so not
knowing anything about it. All I can tell you is that
it sounds 'too good to be true'. A traveling wave antenna
is usually one that is quite long in relation to the
particular frequency it's used on. The antenna you
speak of doesn't sound like it's long enough to be a
travelling wave antenna anywhere. If you find any
information about it, I'd like to see what it is.

Now why would I go and PAY for a license when I got my license, AND upgrades for free.. Oh, sorry, I did have to earn them with a little studying and such.. My club offers testing free.. No money exchanges hands.. And I can now talk world-wide on the Extra bands..

Just quit tryin to cheat the system, sit down with the manuals and get studying.. And if you want to take a test for free.. First Saturday of the month, Geo-Physics Institute, UAF, Fairbanks, Alaska.

They are some sort of bright colored steel. The same type of finish you get on coffee cans - except heavier duty. The cans themselves are more heavy duty - at least as thick as a coffee can, only they don't have the horizontal "ridges" that are on food cans - they are straight sided and smooth. The magnet works pretty good on them.

>
>Look closer, Jim. Many of those NALs were issued for jamming violations
>by code-tested hams using CW (continuous waves).

Hold it right there. You're trying to weasel word by using two different definitons for "CW".

I wrote "MORSE". Not "CW". My statement:

"To my knowledge, there has not been a single NAL issued to a ham for violations committed while using Morse on the ham bands for at least the past 10 years.."

is still true.

Do you have a counter example? Point us to an NAL in the past ten years where the FCC says a ham was jamming or doing obscenity/profanity using Morse.

I regularly check the enforcement logs. They do NOT say the offenders were "using CW". They do say the offenses are things like "deliberate and malicious interference", "use of obscenity" and such. Other offenses include license test irregularities, operation of uncoordinated 2 meter FM VOICE repeaters in such a way as to cause interference with coordinated ones, operation outside the ham bands or the licensees privileges (on VOICE). Nothing about Morse. Not a peep. Nada. Nil. Nothing. Zip. Zero. Zilch.

Of course that may change, 'specially since one guy had his license changed so that HF Morse is the only mode he can use on the ham bands.

> Human nature doesn't
>change when someone uses Morse code.

Maybe it changes, maybe it doesn't. Doesn't matter. What matters is the BEHAVIOR. And from FCC enforcement actions, the BEHAVIOR of hams USING Morse on the ham bands isn't a problem at all. The behavior of some hams using VOICE on the ham bands IS so much of a problem that most of the FCC's enforcement actions are aimed at violations committed using the voice modes.

Just simple facts.

>Morse code simply is not an appropriate vehicle for supporting emotional
>outbursts.

Maybe it is, maybe it isn't. Again, it doesn't matter. What matters is the BEHAVIOR. From FCC enforcement actions, it's clear that the BEHAVIOR of hams USING Morse on the ham bands isn't a problem at all.

What you're saying, Cecil, is that Morse use causes hams to behave themselves much better on the air. That's a good thing!

Spoken language is.

Maybe yes, maybe no. To those fluent in Morse, one is as easy as the other. I can send obscenities as easy as I can say them - maybe even easier - but I choose to do neither on the air.

Thread:

I'm not an expert on this radial stuff.

But FWIW...

I do recall a series of articles in QST by Jerry Sevick [W2FMI?] a few years back where he conducted and documented, what I would call, definitive experiments on this matter.

He experimentally tested various ground mounted verticals and published lots of results for the tests over radial fields with varying numbers of radials over quite a wide range. He actually put the radials out in bundles and then separated the bundles one by one to see the effects, etc...

I believe a search through old QST's looking for the author Sevick on the subject of ground mounted verticals should come up with the pertinent articles.

Me...?? I just throw out all of my old ham magazines... heh, heh.

Hello
I have just gotten an Old HyGain 12AVQ 10,15,20 meter vertical.
I think I have all the pieces, but it sure dosen't tune up very
well.

Anyone have a copy of the old manual, or could help me with
setting the various lengths of tubing, etc.

How long should the traps be apart? How long is the top small
tube go. Any help will be appreciated.

Dennis

815. Re: Homebrew Antenna sugestions for 462mhz please

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-07 22:34:35 UTC
From: tom_bruhns@agilent.com
Message-ID: <93aqtr$82d$1@nnrp1.deja.com>
Source record: 172588

The CB SWR meter probably won't be very good at 460MHz. You could,
however, test it if you can come up with a decent 460MHz load. If you
happen to have 100 feet or so of RG-58, try terminating that in a
nominally 50 ohm load. (47 ohms is fine...even a short or open isn't
too bad!) On the other end, you should measure pretty close to 1:1 SWR.
The coax attenuation will make any load show a fairly low SWR. But in
any event, I wouldn't worry too much about a 1.5:1 SWR. Question is,
does it WORK to communicate with?

Cheers,
Tom

816. Cushcraft R7000 Vertical Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-07 22:35:23 UTC
From: Carl Sherman <csherman@flash.net>
Message-ID: <3A58EEE2.119943CA@flash.net>
Source record: 172587

Have an R7000 HF vertical. At about six months Cushcraft replaced two of the three traps for me, to repair an intermittent problem. That fixed the problem for eight months--now it has failed again in the same way. 10 and 12 meter bands are okay, but the others show high VSWR with intermittent brief periods of proper VSWR.

Two years ago, this was a hot new antenna with Cushcraft, but it has since been completely discontinued. The antenna must have a serious design flaw. Has anyone had any experience that would assist me to determine what the mode of failure is for the R7000's, and what one could do to permanently fix the problem. I typically run continuous digital modes at about 50 watts or less. Don't think that should hurt the antenna.

Any experience out there with repairing R7000 traps?

Any assistance would be appreciated. Live in a "Restricted" community, and the R7000 has the most pleasing appearance of all the multi-band verticals I know.

73,
Carl Sherman W5SBH

Maybe miscreants should be sentenced to communicate only in Morse if that cleans up their acts. Punishment enough too. Be sentenced to master Morse. Would it work? The languages I know have about the assortment of expletives and I`ve seen little difference in their usage. Why they would not encode into Morse as easily as Baudot or ASCII, or why that should make any difference to the user seems extremely strange to me.

Best regards, Richard Harrison, KB5WZI

Source record: 172593
Cross-posted to: rec.radio.amateur.antenna,alt.ham-radio.hf

Hi Robert:

I don't have that model, I have the one that covers 10 to 30MHz. Here is my take on the device. The lower the tuned frequency, the narrower the bandwidth. On 28MHz the bandwidth is about 200KHz at 10MHz is only 10KHz. You will notice that as you tune away from the tune point the signal levels will drop allot, but you will still be able to hear everything you could if the antenna was tuned to the listening frequency. Remember receivers have a very large dynamic range. As for tuning it by the motor noise, this is a design feature/bug. The motor makes allot of RF hash when it runs, so as you tune the antenna through the frequency your listening to the noise will peak. This is very useful as there is no way to tell what frequency you last tuned the antenna to if you forget, so using the motor noise to get close is a big help. You will find the performance compared to a full size dipole gets better as you go higher in frequency. If you mount the loop horizontal, do what the manual says about minimum height. Get it too low and it will not work. The narrow bandwidth can be a help. I used mine at field day on the PSK31 digital station and I was able to operate on 20m at the same time as the 1KW (we went QRU) phone station was. My loop had some problems when I first received it. There were very many bad solder joints inside the loop its self and a loose bit of solder shorted out the power on the feed line whenever I put the antenna horizontal. After I fixed it everything worked well. The only other problem was the performance dropped slowly off and sometimes on damp days I couldn't get the swr down. I opened the loop housing up and found 7 wasp nests inside and 50 wasps living inside the metal tubing that made the loop. The answer is to make the plastic housing fit a bit tighter so the bugs can't get in. Don't make it air tight or you will have water problems, just keep the bugs out.
Anyway it worked for me

Hi, Gary-
I have always looked foreward to reading your posts. You have a sharp
mind and have contributed so much to past discussions. It is a shame that
the no/pro code debate has proven so divisive.
Language is a living, breathing thing. It is adaptable. It changes, it evolves

over time. People use it in different ways, and for different reasons. Some seek to enlighten, some to obfuscate. When emotion clouds the mind, reason suffers.
I can do a callsign lookup on you and note your license class and surmise some things about your ham radio CW politics that seem to fit your newsgroup personality. That is sheer guesswork, of course.
You apparently chose not to overcome the 'hazing ritual' and obtain an extra class ticket. Makes no difference to me. I don't respect you one bit less for that. Your presence in this newsgroup has been very positive and enlightening.
Getting overly precise and technical can lead us away from the truth.
I use the english language in a different way than you. My adaptation is equally valid and constructive, whether you wish to accept it or not.
Take my assertion above that language is "living". You can tear that argument apart on technical grounds if you like- point out that language is a dry, technical thing, a symbolic construct used to communicate information and no more alive than, say, mathematics. Well, math is a language too. I choose to speak in metaphor, perhaps you do not. If I succeed in making myself understood, my approach is as valid as yours.

CW is both an encoding of language (you agree) AND a spoken language unto itself. The second point would not be valid if I were the only person who believed it. The fact that it is a shared belief (and reality!) makes it so. You can split hairs so as to either support or refute this. The most elegant of proofs cannot make what is true untrue, however.
Pig latin is a spoken language. It is actually a language superimposed on a language. 'Speaking in code' (using special code words) is a spoken language. Again, it is a language superimposed on a language. Used often at boring social gatherings to persuade spouses to 'call it a night'. The simple fact that CW is communciated through atmospheric vibrations into the ear/brain interface makes it a spoken language just as surely as human speech is. That fact CW is derivative, an encoding of spoken language is irrelevant. The fact that it would not exist if the spoken language did not first exist is irrelevant. CW has taken on a life of its own, has its own accents and other nuances, has words (yes, encoded spoken words) which are apprehended by skilled operators AS words, has its own culture, and evolves over time just as spoken language does. As always, it devolves down to an experiential dilemma- "you just had to be there". If you have not personally experienced the fact certain that CW is more than encoded language, that it is a spoken language, your denial is understandable. It is like the classical grade school experiment with permanent magnet, paper, and iron filings, which establishes experientially to a near certainty the existence of invisible magnetic fields (further substantiated later with very rigorous mathematical proofs for the technically minded). Language can be your servant or it can make you its slave. It is your choice. But truth is.
And the truth here is that a lot of us use CW as a spoken language. It matters not whether you accept this as truth. Our viewpoint is every bit as valid as yours. I use language to paint with a broad brush. I use a lot of metaphor. You choose to use language with laser, micro-surgical

accuracy. That is OK, that is equally valid. I sometimes use grammatically incorrect constructions as a part of my conversational style (incomplete sentences). It still succeeds in communicating.
It all reminds me of those cute television ads a generation ago in which two cute models nearly get into a fist fight about whether Certs is a breath mint or a candy mint. (Turns out Certs is two, two, two mints in one. Kaching!) Or maybe it is like the three blind men and the elephant- no code, pro code, and "why don't you guys all shut up and go back to operating!"
Please let us live, Gary- CW ops are actually pretty nice folks, too. :o)
73, David

Could it be that the folks who wrote your dictionary were not fluent in Morse?
Nor knew of anyone who was?
By any reasonable definition -and there are several that apply in my Funk and Wagnalls Standard College Dictionary- when a Morse operator is proficient to the point that he hears the code sounds directly as words, and does not go through the code-to-letters-to words translation, Morse is indeed a language, and you know it. Your assertions to the contrary just show your lack of knowledge on the subject, your tenure as a ham notwithstanding. Also shows your efforts toward destroy your "favorite" mode.

Some guys told me for the reception on TV for UHF-VHF that RG6 is a good coax (not the best but a good one...) and I would like to know if there are many kinds of RG6 because you specify that it must be double shielded. Are there RG6 single shielded ? I know that Radio-shack sells RG6.

I have to say again that I will need about 120 feet of coax...

Also I have an amplifier from Radio-Shack that I can install near the antenna.

I'm living in Canada.

As many of us silently await promised parcels of registered mail from Belmont, it brings to mind Samuel Beckett's morbid story entiled "Engame". The central character, an eccentric yet powerless tyrant (ironically) named Hamm, perches on his throne made from a mechanic's creeper topped by a chair and entertains fantasies of royalty. Waxing phiolosophical, Hamm proclaims, "Nothing is funnier than unhappiness. We still find it funny, but we don't laugh anymore." An off-stage voice responds lamentingly, "Then have you not had enough???" But Hamm clearly has not, and he goes on--and on--and on--until his life-weary head drops to his chest.

You can create your own definitions as long as you like. They become fact when generally accepted. I think that will never happen.

Language, the word, derives from the Latin word for tongue,"lingua". Sounds come from many sources. Those that roll off the tongue are "language".

The sound of a bell may mean food to a conditioned dog. It is not language even to the dog.

"ARSK" may be a tune that means the end of a Morse message to you. It didn`t come from a tongue as a normal practice and it is not language, no matter how little you must think of it to gain its significance. The fact that you don`t have to recognize individual letters, or even words, or much less parse the sentance, has nothing to do with the definition of language. Morse is a code, and not a language. Repeating your mistake a thousand times will never make Morse a language. Dr. Paul Joseph Goebbels was without any doubt correct in declaring that if you repeat something often enough, a lot of people are going to believe it. But repetition won`t make it correct. A fact is a fact.

As Cecil said, Morse is relegated to hobby service and is no longer used for serious pursuits. The word hobby can be properly contrasted against the word serious to gain a perspective of their meanings in which one excludes the other.

I am not trying to destroy Morse code. I am delivering a factual message that you don`t want to hear. Crying, "No! No!, it`s not so!" does not alter the truth in the slightest.

The smartest thing to do is to make the best of the situation.

Best regards, Richard Harrison, KB5WZI

Let me see if I understand this:

CW is the greatest thing since sliced bread, is its own langauge, etc
etc.

Yet CW will _die_ if the testing is eliminated?!??!?

What's wrong with this picture?

Hey, don't get me wrong: I have nothing against CW the mode -- I may
even learn it one day -- but I won't learn it just because it's a
required knowledge -- it's just another mode, not the Holy Grail.

Fifty years ago Morse testing made sense, for more than one reason. Not
the least of which that Morse had valid miltiary, merchant marine, etc,
uses. Those uses are now gone. Hams are the only ones using Morse. (As
Cecil would say, we're not really using Morse per se).

Why test? Can Morse not survive without the forced learning in order to
access the amateur HF allocations? If CW requires forced learning and
testing in order to survive, then it deserves to die.

I, of course, believe that CW will survive and thrive even without the
forced testing. The technical tests will do an admirable job of keeping
out the trash that's not already here (check out 75 meters phone... I
even know one (young) Extra (_old_ 20 wpm code Extra!) who much prefers
code -- it doesn't betray his age, and other inconsiderate ops don't
tell him to stop playing with Daddy's radio because of his voice.

I don't expect to change many minds with that statement, but I thought
it needed stating.

But, yes, most CW ops on 80 meters (and elsewhere) are much more polite
than the stench on 75.

Apartment dweller and a ham new to HF having reception problems. I am using a 20 meter ham-stick and PSK-20 20M QRP kit. I have a Vice Grip based hamstick mount from Transel. I simply screw the ham stick in and clamp the vice grips to anything I can. I am also using a 50 foot RG58 coax cable.

I have a few questions please:
1) I am considering adding a tuner to balance the antenna to the load.
2) I do not think that I am not getting a good ground plane. I am on the second fllor of an apartment and am placing the antenna on a small deck we have. There is a drain pipe not far from where I mount the antenna. Is this a good item to connect to make a ground plane.

I think in the not too distant future, those that understand CW will start to die out. However, it will become a status symbol of something belonging to the "old timers". Next you will see many learning it to gain the status. CW will never die out.

hello there. I just purchased a htx-100 for 10 meters. when it arrived i went out & got the "Deluxe" 10m/11m antenna also from radio shack. my problem is this. with this antenna the radio only lights two of the "rf power" lights while talking loudly. now when i hooked up my cheap crappy cb antenna the radio produced full output (while talking) and recieved at least more noise. although it's smaller & i'm sure not as effective as the "deluxe" how could this be? One idea i had was to return the deluxe antenna & buy one of those white whip antennas rs has for cb do those work on 10? ok well if anyone has ideas please respond. thanks... 73

Could it be that one is AM and one is SSB? The carrier is always there during
AM transmitting. The carrier is suppressed for SSB and RF is effectively only
there during speaking.

Obviously, if both antennas are functional, one antenna is resonant and the
other is off-resonance and needs to be tuned. Got an SWR meter?

Your posts over the last year certainly would lead one to believe
differently. Your support of the freebander and no-code groups has been
amply noted by yourself any number of times.

What purpose, constituency or group are you now serving? Why do you think
you have to "...deliver a message..." to anyone?

Perhaps you could just "...make the best of the situation..." and enjoy the
no-code status that you have helped bring about. Continuing a crusade
against CW surely isn't going to help you win friends and influence people.

Jim, I don't know where you are getting your information from, but I think
your information is not correct. The number of re-tests is usually very
limited and focused on a specific exam session in question. They usually
ask you to test at a different VEC, not necessarily an FCC office.

Butternut HF6VX and HF9VX both are more aesthetic looking than the
Cushcraft, and perform quite well with a few ground radials.

A CB antenna will present a mismatch for 10m, although not very large.
A high enough mismatch can cause the RF output meter to lie to you as to
actual radiated power. If you have access to a dummy load sufficiently
large to handle the HTX-100's output, I'd check the radio on the dummy
first. Then, see if another ham's 10m capable HF rig can produce
reasonable power on the 'deluxe'.

But the CB antenna will not be optimal, unless you shorten it for best
SWR. The fiberglass helical whip is going to be difficult to tune
properly, unless you use an external tuner.

Also, test in FM mode (the 100 has FM, right?) as the power will remain
constant regardless of audio. I know the new HTX-10 has SSB/AM and FM
at 25 watts.... but I forget what the 100 had.

Good luck!

Check the Cushcraft web page and you should find what you need.
Go to: http://www.cushcraft.com/support/tlai.htm and down load the pdf
file for that antenna.

Neat. Someone actually thought of not charging. Of course, my first licenses cost nothing - it was just the 60 mile (one way) drive to Buffalo that cost a bit of time and money (gas, thruway tolls, parking, etc.). The cost is actually minimal anywhere. I think I paid $5.90 when I decided to get back into amateur radio and tested out in 1993 (after letting my tickets expire over 10 years earlier). Whats the cost today?

Trying to come up with a SWR meter that will work at 460MHz. I have tried receive on it mounted about 15ft up and it definitely does better than the antenna on the HT. Don't want to fry the output of my HT so I am waiting till I can get a reliable check of SWR before I really try out the transmit, also ordered some LR400 cable to use on it. I will post more later. Thanks for all the help and advise.

>

Think whatever you want. My wife is a schoolteacher and there are several dictionaries in the house. I've even got a couple here in my radio room. Every one shows you to be wrong. And the definition of CW as a language is not mine, I inherited it along with many other CW fans - those who have learned it to fluency.

> Language, the word, derives from the Latin word for tongue,"lingua".
> Sounds come from many sources. Those that roll off the tongue are
> "language".

It's curious that you, who might otherwise seem to be an educated fellow, insists on holding this single word -language- true to its ancient Latin roots, while the remainder of the English language has mutated and evolved continuously over the millennia, even vastly over the past century. That is most curious, and clearly indicative of the blinding bias that has clearly led to your posture.

> The sound of a bell may mean food to a conditioned dog. It is not
> language even to the dog.

You might as well begin your argument with the many publishers of dictionaries, for you could indeed call such a means of communication a language under some dictionary definitions.

>
> "ARSK" may be a tune that means the end of a Morse message to you.

No, actually it means I'm signing clear with that station and turning it back to him for his last transmission. The "end of message" prosign is BT. Usually means there is another to come.

It
> didn`t come from a tongue as a normal practice and it is not language,
> no matter how little you must think of it to gain its significance.

So since none of the words we're exchanging here via keyboard rolls off the tongue I guess we're not really using a language, then. Gotta be spoken, right!

The
> fact that you don`t have to recognize individual letters, or even words,
> or much less parse the sentance, has nothing to do with the definition
> of language.

So lets just review the definition of the word language in a couple of REAL sources:

1. "Webster's New World Dictionary of the American Language" shows five definitions,two of which would apply, one directly:

"Any means of communicating; the ability to express or communicate by any means".

2. "The Harcourt - Brace School Dictionary" has a very good one:

"Any means of expressing ideas or emotions".

3. "Webster's New World Dictionary" : "Any means of communicating".

4. Then there's the "Funk and Wagnalls Standard College Dictionary", over 2K pages: "Language, n.: Transmission of emotions or ideas between any living creatures by any means".

Surely those are sufficient to make the case.

>Morse is a code, and not a language. Repeating your mistake
> a thousand times will never make Morse a language.

Golly, Rich, did you ever consider updating *your* language set out of the Roman era and into the 20th century? Perhaps, even, to the 21st?

> As Cecil said, Morse is relegated to hobby service and is no longer used
> for serious pursuits.

You are more than welcome to hang on Cecil's every word. Most of us know better than anything like that. Cecil's veracity is always suspect and subject to his Agenda du jour.

> The word hobby can be properly contrasted against
> the word serious to gain a perspective of their meanings in which one
> excludes the other.

Amateur radio is unique among hobbies. If you don't know that your knowledge of the Service is less than complete.

> I am not trying to destroy Morse code.

Just doing your part, of course

> I am delivering a factual
> message that you don`t want to hear. Crying, "No! No!, it`s not so!"
> does not alter the truth in the slightest.

So you might want to take your own advice and stop it, then.
You seem to think that just because you (along with everyone else, by the way) know that the world outside ham radio has moved away from radiotelegraphy that we hams who still know it, like it and use it should just consider it dead as a useful mode for handling traffic -and just ignore its lengthy history exactly that - eminently successful handling of communications traffic.

We say is that is nonsense. Regardless of what technology has brought, the usability of radiotelegraphy has not diminished at all. In fact it, too, benefits from advances in technology such as DSP and other signal enhancing techniques, right along with the other modes. If DSP is good for enhancing SSB communications should we just assume that it is no help whatever to CW? That's stupidity.

So kindly stop the assault. It will be countered. Depend on it. We know the end game that is desired by the Anti-Code crowd is to eliminate radiotelegraphy from the bands, regardless of what they say. It's an incremental game plan.
So all your posturing is for nothing. Maybe you don't intend to help see CW from the scene, maybe you do. In either case, you need to understand that you're helping to do just that by your derogatory comments. So you can expect them to be countered with true facts.

> The smartest thing to do is to make the best of the situation.

So who is not? You seem to think that you can't benefit from a little education yourself and continually show your dearth of knowledge on the subject of radiotelegraphy. Moreover, you try to foreclose anyone from even stating facts about it. If that's not dodging reality I can't imagine what you'd call it.
Nothing you have said that was truly factual has been challenged. What you stated that is known to be less than factual has been, and I can assure you, will continue to be.

Substitute "technical knowledge" for "Morse" in the above rant and you have the current mantra of those who would further dumb down the ARS.

>It isn't the mode that gets busted. It is the operator.

Agreed! The point is that the operators who get NALs are NOT using Morse.
Almost all of them that get NALs for operating violations are using voice
modes.

> I would also
>venture to guess that most of those violators have passed the CW test.

Sure - at varying speeds. But I'm not talking about the test at all. I'm
talking about the USE of the mode, and how its users behave themselves on the
air.

All of the violators also passed WRITTEN tests, which included questions about
the regs they violated. The written tests didn't stop them from breaking the
rules.

> That
>kinda kills your observation thing.

Nope. Not at all. The observation is about the USE of the mode, not the TEST.

>How many of those violators are no code
>techs?

A few.

>Someone said in another post that nc techs were the largest group of
>hams so they should be flooding the offices with complaints against them

I never saw that. Sounds like a great idea. I've posted very similar ideas.

You posted that "thorough" written tests weren't needed.

>As for the terrible state of CB i still don't understand everyones problem.
>From what i have heard on HF, cb is 100 times better everywhere i have ever
>turned one on. I am in Chicago and have never heard any problems on CB.
>Back home in a smaller town, cb was much friendlier than any of the ham
>bands.

The experience of many others is quite difference. I've never transmitted on cb, but I've listened there many times in the past 35 years. All sorts of rules violations were and are common. Excessive power, spurious emissions that cause RFI, off frequency operation, jamming, obscenity, all sorts of stuff. Most of all, an attitude that the rules don't matter. Are all cb's like this? No, of course not. But far too many are.

What cb folks do on their channels doesn't bother me. But when they invade the ham bands illegally, or when hams get blamed for problems caused by illegal cb operation - that bothers me.

>> That's what folks like me oppose.
>>

Hello

I have just gotten an Old HyGain 14AVQ 10,15,20 and 40 meter vertical. I found out from looking at pictures it wasn't a 12AVQ as I had thought.

I think I have all the pieces, but it sure dosen't tune up very well. --- I think I might be missing some little thingee that goes on the top ??

Anyone have a copy of the old manual, or could help me with setting the various lengths of tubing, etc.

How long should the traps be apart? How long is the top small tube go. Any help will be appreciated.

Dennis

852. Re: EZNEC treatment of two metals?

Newsgroup: rec.radio.amateur.antenna

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A59618D.EDD3158D@eznec.com>
Source record: 172524

Metal resistance seldom makes a significant difference with these antennas, so you can choose the resistance of either one without affecting the result noticeably. In other antennas, loss in one part of the antenna usually dominates, so you should select the values appropriately for this part. For example, if you have a small loop made from copper tubing which is mounted on a steel tower, use copper.

The loss in an antenna is proportional to the square of the current, all else being equal. So another way to determine what part is likely to have the most loss is to look at the current. (Of course, wire diameter is also a factor, but looking at current alone is a useful rule of thumb.) In the above case of the loop, the loop current is a great deal more than the current in the tower, so copper is chosen. If you have both a quad and Yagi in one model, chances are you're exciting one of them, and the other is parasitic. If so, the excited one will typically have a lot more current, so its loss will dominate and its metal should be used in the model (although, as I mentioned earlier, quads and Yagis generally aren't very sensitive to wire resistance -- except perhaps for actual wire Yagis or very short ones).

This limitation came about simply because of lack of space on the DOS version screen for another column. Time prevented adding it to the Windows version, and I have yet to see a case where the limitation has prevented accurate modeling, so individual wire loss didn't have a high priority. Widening the Wires Window might create a problem with plain VGA adapters, but these are getting scarce now, so you'll probably see individual wire loss specification in a future version. Not because it's really needed for accurate modeling, but because quite a few people feel they need it.

bozekk,
It sounds like you may not have a ground for that
antenna. The ground acts as the 'other half' of a
1/4 wave vertical and with out it, I doubt if your
getting a very good match to the radio. A counterpoise
connected to the 'V-grips' as a ground may help a lot.
A counterpoise is merely a 1/4 wave of wire, or an
elevated radial, if you will.

Curtis,
I would say it just depends on what would be easiest
for you, and what the roof looks like. As long as it
has a good mechanical connection to the roof, and you
follow the instructions for the particular antenna you
have, it should work fine.

If it's the deluxe magmount that is about 54-58 inches tall, it's a
fairly decent antenna. Much better than the smaller white ones. Where is
the antenna mounted? If used on 10m, it will likely need to be trimmed.
The length is set for 11m as it is. There should be a chart with the
antenna that show appx how much to trim. You'll need an SWR meter to do
this as the car will effect. Your length may not exactly match the
chart. I don't know the metering on that radio. But if the meter reads
average power, you should only show about 1/3 the CW output readings on
voice peaks. Say if you had an average meter, and did 25 watts CW. On
SSB voice peaks you will only show about 8-10 watts on peak if the mike
gain is correct. A true peak reading meter would show appx 25w. I've
used those antennas mounted on the roofs of cars and vans and they did
quite well. Assumming yours the deluxe magmount. It'a about the equal of
a K-40 CB antenna. MK

> fact when generally accepted. I think that will never happen.

Exactly. It is generally accepted among a significant portion of radio
amateurs (who know and like code.) Demographics which even you
might acknowledge point to this obvious conclusion. Lots of hams
still use CW.

> Language, the word, derives from the Latin word for tongue,"lingua".
> Sounds come from many sources. Those that roll off the tongue are
> "language".
> The sound of a bell may mean food to a conditioned dog. It is not
> language even to the dog.

You are the one clinging to the archaic here. The modern definitions and
uses of "language" are numerous, including many non-spoken forms such
as american sign language, computer programming languages, the
language of mathematics, and of course the Morse Code language.
Useage precedes definition, in any case, with dictionaries regularly getting
revised. Remember, language is a living thing. We (humanity) make it up
as we go along. Even my very old 83 Websters Unabridged, which is mute
on the subject of the many computer programming languages of this era,
does clearly state:

" 2. Any means of expressing or communicating, as gestures, signs,
animal sounds, etc." QED. Note the word "any".

You are demonstrating extreme rigidity to insist that the word "language"
only applies to spoken tongues; many will disagree with that view.
You sre so obviously not expert in this area. You are out of your element.
Cunning you are in your linguistic bobbing and weaving, but you will
never succeed in twisting the issue as badly out of shape as your
ham politics demand. Relax, and in 30-40 years we will all die off and
maybe you can then have the last word. As it is, the no code faction has
essentially 'won' anyway, so what the heck is your beef? You derive some
satisfaction from flogging a dead horse? Well, you are the one who
insists that this horse is dead...

That is exactly what you do. Indeed, endless repetition will not make a lie
the truth, but spoken often enough, it can sure fool a lot of people. I bit
my tongue and watched you badmouth amateur CW for many, many months,
until I could no longer stand it. In your comments about repetition, you
are projecting your own behavior onto others.

> As Cecil said, Morse is relegated to hobby service and is no longer used

> The smartest thing to do is to make the best of the situation.
> Best regards, Richard Harrison, KB5WZI

You speak so obviously from emotion, despite your reasoned posturing.
Note your value-laden word choices above: "relegated", and "serious" vs.
"hobby". No amount of words can bury the fact of what a central part
Morse played in the emergence and growth of radio, nor can they change
the fact that large numbers of us "relegated" folks still use Morse on the
radio every day, that it is a *spoken* language to us, and that we love it and
intend to defend it from scurrilous assaults. It will likely survive in amateur
use well into the new century, in harmony with all the other modes,
barring any concerted efforts to prematurely kill it off.
If Morse is so darn lame, as
you make it out to be, why, then, has it survived a century now, why is it
so popular? Why havent *all* hams stopped using it, once they satisfied
statutory requirements for skill? No clique here, either. CW use cuts
right across the entire ham demographic, even today. Because people
like it. Go ahead, blame the overblown 'demise' of ham radio on Morse
skill requirements. The real world is, as always, ever more rich and
complex than that. The personal computer revolution is so obviously
a major factor in our present situation, with Morse requirements a minor
player. What use do todays pampered youth have for ham radio when
mom and pop buy them a cell phone as well as a computer? We will
continue to draw the curious and technically inclined, in small numbers.

The LED lights on the front panel of the radio are most likely voltage derived- so the higher the impedance at the connector end of the coax the more LED's that will light. No antenna at all would most likely light them all up (not recommended). Get a wattmeter and/or a V.S.W.R. meter and find out what is going on.

>Toms example". Thats quite a difference from the theoretical.

Yes, and others report similar changes also. Some people do not.

It depends on many things. When you only have two radials, you are
absolutely dreaming if you think the system is predictable.

One problem is very high levels of RF excite the earth around the base
of the antenna. A second problem is the radials themselves have very
strong fields coupled into the earth. A third problem is the shield
of the coax is part of the system unless you choke the cable at a few
points leaving the antenna.

People have the misplaced notion that because the two radials run
opposite directions radiation from those radials "cancels" . It does
NOT. Radiation cancels only directly above the radials along a line
running at right angles to the two radials, and that is the far-field
pattern where the radials look like a single point in space and the
induction fields are weak enough to be ignored.

No one can assure ANY level of performace when a marginal
radiating ground system is used, and the radiator itself is
exposed to earth and whatever other stuff is around it. Performance is
all over the place.

Another issue is the loss from the soil being exposed to the fields of
the radiator right where they are highest.

All of these losses do not necessarily show up as a high base
impedance, as some think.

For example, I can place an antenna on my truck with a large hat over
the truck, and read a very low base impedance. I can read a resistance
of only loading coil ESR plus an ohm or two on 80 meters.

If anyone thinks the actual ground losses of that system are reflected
in that two ohms, they are dreaming. The high displacement currents
between the hat and truck "short circuit" the ground losses, and make
them less noticable. Yet those losses are still all there!

The system simply starts to act like a "loop", and I see an
artifically low base impedance that makes me think the ground system
is "good".

The only way to know the radiating efficiency actually is through field strength changes when a known good system is installed. It's less bother to just bite the bullet and use 30 or so radials and KNOW things are reasonably good than to spend time making measurements or taking a guess that might not mean anything at all.

Some people do OK with crappy grounds, and some almost can't be heard. The interesting thing is thouse who almost can't be heard always greatly improve and come up to the rest of the boys when they do a modest amount of work.

There are those among us who know all about antennas, yet have had very few antennas to compare and NEVER had a decent signal on any band.

When you look at how many people use verticals on 160 and A-B those verticals against low dipoles, you will find the ONLY people who report nearly equal success with low dipoles are those with small ground systems on the verticals.

Source record: 172538

Talking about radials.
Has anyone done some real life tests and comparison between few radials (2,4,8) and many (60, 120) when over salt water or marsh (or soaked salty beach)?
The point of question is: does the salt water ground (close to perfect) reduce the losses in return currents to the point where few radials are sufficient?
6Y2A - Team Vertical (and mine) experiences with few elevated radials show excellent performance, but could it be (worthwhile) improvement by laying many radials (elevated or on ground) over salt water "ground"?
Practical experiences please.

Yuri, K3BU

You don't mention whether you're using a mobile vertical or one
designed for home use.

If it's one for home use, I'd just go to Radio Shack and get a little
5-foot mast & mounting hardware to get the vertical off the roof and
away from apartment wiring, but without being too much of an
"eyesore."

Radio Shack might also have hardware for mounting to a vent pipe.

I'd look at your roof and then go see what RS has.

"Webster`s New World Dictionary":
"Any means of communicating". (Language Definition)

Ah ha!, so you have a broad definition, and I have a narrow definition.

Did you look up Morse code?

My dictionary defines Morse as a set of dot and dash symbols used in place of letters and numerals.

My dictionary`s definition implies symbols representing yet other symbols.

A Morse code message combines Morse symbols to represent the language of the message. It isn`t the language itself. Never mind, symbols are often confused with the real thing.

I`ll use some symbology. Sailng vessels once upon a time plied the oceans with cargo. Now, they are replaced by motorships. The sailing ships were slow and labor intensive.

Morse code is like the sailing ships above. Motorships are like today`s voice and data transmissions.

Yuri can reason the results. Elevated radials over poor earth are effective when they hide the earth from displacement current which would produce loss in the earth.

Elevated radials over a good conducting surface need only to provide sufficient capacitive coupling to that good surface.

Best regards, Richard Harrison, KB5WZI

While I disagree that CW qualifies as a distinct language (it is a medium for conveying language, similar to e-mail or newsgroups, which have their own shorthand expressions too, right? :-)), there are other seeming encodings that do indeed qualify -- American Sign Language is one of the best examples, as the signs are not just alphabetic. Likewise, a computer language isn't spoken (unless I'm talking Z80 in my sleep again -- I have that on tape that my wife recorded....), but only written. Although I'm not rigid about it -- if you want to consider CW a distinct language, then feel free to do so -- but I will continue to feel free to disagree. It's a free country (and internet).

> If Morse is so darn lame, as
> you make it out to be, why, then, has it survived a century now, why is it
> so popular?

Because learning it had been required in order to get your ticket. Period. To get a higher ticket meant you had to get proficient -- getting proficient means using it. Use it enough, and you learn to like it -- just like teaching a kid to eat his vegetables. The statutory requirement wasn't based on 'because it is a useful mode, let's require learning it.' -- no, it was mandated because it was in the Public Interest for hams to know the code to effectively function in communicating with non-hams in emergencies. That reason is no longer valid -- the only reason pro-code-test people want to keep the test around now is that they fear the death of CW as a mode because of eliminating the statutory requirement for learning it -- and you're not a Real Ham (TM) if you don't do CW.

And some like CW, mostly for nostalgic reasons -- although there are those that like it for other reasons. Like a speech impediment. Or a hearing deficiency (code doesn't have to be received by ear, after all). Or a young-sounding voice. Or they're female and don't want the Good Old Boys to know it during QSO. There's lots of reasons to like CW the mode -- but there are no valid reasons to keep the code test in today's world. And CW use won't go away just because the test does -- or is that the real fear? If code learning is mandatory, maybe the Good Little Boys and Girls will learn to like what to some tastes foul and offensive.

> Why havent *all* hams stopped using it, once they satisfied
> statutory requirements for skill? No clique here, either. CW use cuts

If you have to learn a skill by mandate, might as well use it, right?
Or you learned to like it. Why force the issue by testing though -- is
CW not attractive enough to get new folks using it by itself? Is
mandated testing the only way to bring new CW blood in? I think not.
CW can stand on its own, by its own merits, without any mandate.

Source record: 172547

I'm in the process of re-building a KT34XA. My biggest problem is how to remove the residue/hardening material left behind from KLM's "protective paste". The material has hardened like a rock and although I could leave it there any reassemble the antenna, I would feel much better if it was removed.

Second question. What is the current thinking on a material to replace the KLM "protective paste" ? I have more of it, but after seeing it harden, I don't think I want to use it again. Is NoLox (?) (the material sold at Home depot for AL to CU connections) any good?

Your thoughts.

Thanks,

Tim K8XS

Kind of hard to calibrate a 100 milliwatt scale on a power meter vs the Bird 43. :-)

It may well have a bad coax connection inside. That sounds like a
different antenna than the one I was refering to. If yours has a big
coil, it's the type I've seen lately on trucks that look like mini-10m
bugcatchers. Seems they should do ok normally with a coil like that. You
can't go by the output lights on the rig. You need to buy or borrow a
SWR meter and see whats really happening. If the antenna sounds dead to
the cheaper one, it probably is dead. Receiving is generally reciprical
to transmitting. If one antenna receives better than another, usually it
will also transmit better. Some exceptions, but 95% of the time this
will prove true. Where is the antenna mounted? Thats very important. It
really needs to be on the car metal somewhere. Trunk, roof , etc. And be
grounded well to the body also. "A magmount doesn't require this if
planted on an area of metal". But any other antenna does. Your meter
probably is reading more than normal because of the high SWR when
mismatching whips. Don't worry about what the lights do on the radio.
They could be set to show anything. Make sure the antenna is right
first, and then just adjust the mike by saying x-ray over and over while
slowly increasing the mike gain. When the meter reading quits going any
higher on the peaks, then lower the mike gain just a bit,and thats it.
If you try to get a high meter reading, you will just end up
overdriving, and will sound trashy, and splatter 10 kc each way your
freq. Or maybe worse..The radio shack meter will work just fine.
Actually, they are pretty accurate for the price. And come with a FS
meter which can come in handy at times. MK

I am looking for a vertical that can be used across 10, 11 and 12 meter operations. I've heard that the Imax 2000 is broadbanded enough and handles the 3 meters fine and without tuning. I've also heard that the Imax 2000 is prone to causing a greater amount of RFI to neighbors.

Does anyone have any experience related to the Imax a/o the Maco, their ability to work across the 3 meters I've mentioned, and their relative RFI.

So by your definition you would eliminate the American sign LANGUAGE for the deaf?

How about the tonal language of drums used by African tribes? The tone of the drum conveys meaning as is accomplished in speech. No tongue involved here, simply the movement of the hand on the drum surface.

And talking about communication by movement of the hand, sounds to me like CW falls in their somewhere. And before you respond that a computer can send CW without a hand, my computer talks without a tongue. This argument has reached a par with how many angels can set on the head of a pin and the results are the same.

I think I would accept a broader definition as being able to communicate. That is, unless it is more fun to argue than agree...

I live in an apartment on the second floor. I have an outbacker mobile antenna and plan to set it up on the balcony and setup counterpoises for the 10-80 meter bands. I have a few question.

1) Can I hook up all the counterpoises at the same time, or if I can only have the one for the correct band hooked up at any one time?

2) I plan to run them all tie-wrapped together, is that OK, or do they need to be spaced?

3) the counterpoises for the 10-20 meters bands will drop vertically to the ground, however, the lower bands will have to run to ground level then run along the ground. Will that work?

You make some very good points, Lamar- thank you. This entire discussion will become moot in any case when the WARC boys get together and drop the world requirement for Morse proficiency. Our FCC will soon follow. What I find hard to imagine is that we will be testing for everything else we authorize- with the exception of CW. Yet we continue to authorize the use of the mode on the bands? It sounds like a prescription for chaos. Would we continue to have FCC-mandated sub-bands for other modes? How about CW sub-bands? Seems to me it leads to a sort of progression where CW loses existing exclusive band segments, however they presently happen to exist. Mix the modes all together and CW would definitely be the first casualty. It is a lot easier for the phone and digital mode ops to tolerate on-frequency OOK, the converse is not true. Trying to copy CW under the racket of these other modes is oppressive. Your arguments above are persuasive, and my initial reaction is to agree- sure CW could stand on its own merits because people like it. The more I think about it, however, the more I am reminded of the pressures for bandwidth among 'competing' modes, especially phone, which is such a big user. I am reminded of the open hostility arrayed against CW, and I reach the conclusion that dropping CW testing in return for authorization to use the mode essentially pulls the plug on it. I hope I am wrong on that point. We start to see in a few years. You can fit a whole bunch of stations in a small sub-band with CW, and theres a lot of fun to be had with plenty of hams who do like the mode. In the same bandwidth you can fit only a small handful of phone chats. It makes sense to me to try to preserve the mode if demand continues, and so far, the demand is definitely there. But that is not the direction we are heading.
Nostalgia does not explain my love for morse, nor do I have any of the impediments, deficiencies, or other hangups you alude to above. I just love the mode, and find it has a special and unique quality. There is more of a sense of adventure than I find in the other modes. They get the job done, and I inhabit them fairly often, but CW is where I truly live.
Whether it is or isn't a language is a minor point. Most every dictionary in the english language supports my view. Basically, if it is a means of communication, you can call it a language. It doesn't really matter to me whether everyone can see that or not. Morse, spoken english, ASL, C++, mathematics- they all convey thoughts, feelings, instructions between complex intelligent systems, whether living or not, and the ones which utilize air vibration and enter the ear/brain interface of a human being most certainly qualify. Those who share my love of CW generally also see this. Where we have consensus, we begin to build 'reality', and when we have a sufficiently large and stable consensus, that reality is affirmed by means such as printing dictionaries. Most of these I have seen lately are unequivocal on the subject. 73, David K3KY

Agreed! My comments were not meant as a put-down of the Handbook, but simply an
explanation of what its role was meant to be. There was hardly a book with more
radio-info-per-dollar.

There was at least one case of a serviceman stranded on a captured Japanese
island in WW2 who evaded capture and used the ARRL Handbook to build radio gear
so he could listen to the outside world.
>
>You mention the explosion of tube types in the 50's and 60's. Yes,

Yep! Compactrons often simply repackaged existing designs.
>
>The TV tube industry strove to drive production costs down to the
>point where they could build the equivalent to the radio's
>all-american 5 (5 tube receivers).

And they did, in relative terms. A compactron (and its socket) that did the work of two or three older types did not cost 2 or 3 times as much to manufacture. I think there was a set of 2 or 3 compactrons that were meant to do the AA5 thing.

Another driving force was simplifying wiring layouts and PC board design. An outfit like RCA could easily justify a new tube type if it saved a few pennies manufacturing cost because PC board traces were simplified. They could also develop new types that used fewer/cheaper other components.

> Solid state moved faster.

A bunch of things happened there. "Solid state" was "sexy" back then - it implied space age modernism and progress, even if the TVs didn't actually produce a better picture. Once the sales folks got the public believing solid state was better, tube sets were doomed, no matter how good they were.

The size, weight, and power advantages of solid state meant lower manufacturing costs, and smaller/lighter chassis, too. End of story.

Similar stuff happened to hamgear in the '70s. Often the new solid-state gear had poorer specs than the tube stuff, but lots of folks didn't understand "blocking dynamic range" and "third order dynamic range" and "phase noise" so they bought Kenwoods and Icoms instead of Collins and Drakes.

Yes, the handwriting is on the wall -- "NoCode, NoCode, total gone
Morsetestin'"

> What I find hard to imagine is that we will be testing for everything else we
> authorize- with the exception of CW. Yet we continue to authorize the use
> of the mode on the bands? It sounds like a prescription for chaos.

Why? We don't test that one can understand frequency-shifted SSB
transmissions now. It is assumed that an operator can understand such.
We can't (without programmed help) understand PSK31 raw from the
receiver -- but the mode is authorized. CW can be received and sent
from computer -- no manual codec required.

> Would
> we continue to have FCC-mandated sub-bands for other modes? How about

> exist.

Eliminating the CW test != Eliminating the bandwidth for the mode.
Although lower CW usage might cause the FCC to reduce the CW band
allocations, the FCC isn't likely to do away with the CW subbands
anytime soon.

> I am reminded of the
> open hostility arrayed against CW, and I reach the conclusion that dropping
> CW testing in return for authorization to use the mode essentially pulls the
> plug on it.

Methinks the open hostility is mostly due to those who are hostile
feeling pressured into learning what they feel is an archaic mode of
communication. Like the adults who will not eat cauliflower now simply
because they were forced to do so as kids (and there are many examples).

[snip discussion on why he loves CW]

No arguments there -- feel free to enjoy CW long after morse proficiency
testing is eliminated.

> from loving steam.

Correct. Some people enjoy flying kites, too, even though there are
numerous other types of flying craft available. By your own words,
you have destroyed your argument that CW should be abandoned
because, in your view, it is outmoded. Clearly, it is enjoyable to some,
whether they, you, or anyone else views it as outmoded or not.

As to "outmoded" in general: outmoded does not equate to
"unuseable", "not useful", "of questionable utility" etc. CW,
whether you consider it outmoded or not, can be and is used
as a means to get the message through, whether or not other
means fail.

It is also used as a means I built of controlling electrical devices
for three disabled people, when all that was needed was
easily satisfied by counting pulses. This is not a ham radio
application - but I wouldn't have had the capability to do
it without understanding CW as a communications means,
and I gained that through ham radio. And therein is the
relationship to ham radio. This does not say that someone
else could have done it by some other means, without knowing
about CW or ham radio. But it does say that CW has utility,
and that the CW requirement I had to fulfill for ham licensing
meant at least 3 bedridden people had a small measure of
assistance and independence.

Hi All,

This "language" issue seemed to be messed up by factors that were rhetorically forced upon the Code. One of those artificial factors was the declaration that Morse has a one-to-one mapping to a Roman character, which is nearly true, but has a weak bearing on the nature of language.

Yes di-dah maps to A, but that does not make di-dah equivalent to one character in Morse. It is more than obvious that dit is one character in Morse and dah is another. The pairing of di-dah is what is called a morpheme which is a linguistic element of language denoting a larger, more abstract language component. di-di-di-dah is another morpheme composed of the elements di and dah with repetitions in an unique pattern. Each morpheme has a one-to-one mapping with a Roman character and as such presents a lowering of efficiency in coding the translation. The lowering of efficiency is the mapping of a Morse morpheme to a Roman character (rather than a Morse character to Roman character), hence a step backwards in translation.

So the more basic question is what constitutes a language? A character set (spoken or written) that combines into morphemes that combine into tokens is one good start for a defintion (or at least its expressions). Syntax is higer, more abstract element of language which is the relationship of tokens composed of morphemes which are composed of characters. However, Morse as a language begins to strain when it comes to this analysis. There are no syntactical rules in Morse that are uniquely different from the language in which the message is intended to be translated into. This is probably more the issue that some posters were trying to communicate when they averred that Morse is not a language. So to simplify:
dit Morse character
dah Morse character
di-dah Morse morpheme (or possible token)
di-di-dah another Morse morpheme
di-di-di-dah yet another Morse morpheme
di-di-di-dit_di-dit Morse token
di-dah__dah-dah_di-dah_dah-dit a Morse syntactical expression of two tokens.

Is Morse a language? It conforms to commonly held definitions (no, not those found in Webster's) and is not simply a mapping. Is this language efficient? That is not a functional requirement, but given a limitation in the conduit of information, it is a matter of those limitations enforcing its use, rather than one of choice for convenience. Are there better mechanisms? Yes, but they too exhibit the same issues when it comes to efficiency. They may be more efficient than Morse, but in and of themselves they are also steps back (especially Baudot).

Correct, however it is very unlikely you would copy any of the NOAA stations in Germany. They transmit on freqs around 162.55 MHz

Most are line of sight range and here in the US we have many of them. Local weather and regional weather announcements are transmitted by computer synthesized voice.

They also have the ability to transmit an alert tone that turns on weather radios to warn of tornadoes, severe thunderstorms, and any other life threatening weather.

Cecil, I'm sorry once again to state what John Cleese would refer to as the bleeding obvious.

Way back in the 1930's 3 people floundered about with digging implements making some measurements AT MEDIUM FREQUENCIES on field strength, or whatever, with a large number of shallow-buried radials. They didn't even bother to measure the conductivity of the ground their radials were buried in. If they didn't have call signs they were still clearly amateurs ! Nothing the matter with amateurs of course.

Then we have ONE radio amateur who, in the 2nd half of the century, makes a few measurements at HF with different numbers and lengths of radial. And even HE doesn't bother to measure ground conductivity either.

And the whole of the amateur radio antenna antenna grounding philosophy is based, according to you and some other believers, on these remarkably few measurements, from only TWO practical experiments. Over a period of 65 years ?

Fortunately, genuine radio engineers have more logical ideas - except the few poorly educated ones who have been brainwashed by the CFA philosophy. Who was it who said "There's one born every minute" ?

Right. And a definition that fits, in either case. When a prificient Morse operator says that he copies Morse as a language, as you would hear spoken words and you say he's lying, that just means you do not understand what he said.

To you Morse will never be a language, and I clearly understand that. But you are simply wrong to insist that Morse is never a language. Clearly under the circumstances described it is. That should be good enough for the both of us.
If not, they you are welcome continue to fight on. I've already wasted far too much time attempting to convey understanding where clearly there is no opening to receive it. End of story.

Robert:

[snip]
> 1) Can I hook up all the counterpoises at the same time, or if I can
> only have the one for the correct band hooked up at any one time?
[snip]

You can hook them all up at the same time, since they are "resonant" at substantially different frequencies they will have only a small interaction with each other.

[snip]
> 2) I plan to run them all tie-wrapped together, is that OK, or do they
> need to be spaced?
[snip]

They need to be spaced. Space them as far apart as possible. If you bundle them all together, then... they simply act as one!

[snip]
> 3) the counterpoises for the 10-20 meters bands will drop vertically to
> the ground, however, the lower bands will have to run to ground level
> then run along the ground. Will that work?
[snip]

Yes that will work, but keep them "spaced" as above.

Note that the counterpoises should be an "electrical" 1/4 wavelength for each frequency/frequency band in use. This means that it is advantageous to "tune in situ" to an electrical 1/4 wave, since parasitic effects due to the counterpoises lying on the ground or close by conducting objects will cause the "electrical" length to deviate from the physical length.

A good way to "tune in situ" is to startwith the counterpoises intially too long, and then trim them to shorter lengths while measuring [not simultaneously while energized to avoid RF burns, heh, heh.] the counterpoise current. Cutting the counterpoise to the length that causes maximum counterpoise current flow will result in exactly 1/4 wave electrical length. If you cut off too much and overshoot, then simply solder the remainder back on. In almost all practical cases the 1/4 wave electrical length will be less than 1/4 wave physical length.

I have used this method of cutting counterpoises to 1/4 wave length "in situ" on several sites and found it to be quite effective in terms of increased transmitted signal strength. Often the 1/4 wave electrical length is almost 1/2 that of the physical length, especially when the counterpoises are buried an inch or so underground.

I have the one for HF and love it! It's small and light weight. I only wish it had a loop so I could attach it to my belt or wrist or something while hanging on the side of a tower. I did make a small leather bag for it so I could attach it to myself. It is light enought that you can hang it from the end of a short coax jumper attached to the coax connector on the antenna and let it hang there while you work on the antenna. I have checked it and it's accurate enought to get by with on HF. I have never carried a bird meter up a tower and checked the swr readings between them. I don't really like the idea of someone transmitting while up a tower below an HF antenna even at a low power! I really wish I had the more expencive "do it all" meter they have now for HF but as I did not get one on 25 DEC I think I will order one now.

Reg, Cec:

I support Cec's assesment, and I believe that Reg is being too cynical here.

I believe that Jerry Sevick did a very thorough job of measuring and documenting the effects of varying of numbers of radials, and their lengths, on short ground mounted verticals including the "relative" effects of ground conductivity.

I believe that he did this at HF and in the second half of the twentieth century. At least that's what he said he did and the publication dates are between 1950 and 2000! So Reg, what's your point?

Jerry is definitely not a lightweight when it comes to tests and measurements. He documented his measurements very well.

Reg, what are your objection to Jerry's results? What are your concerns?

If you have trouble getting it to operate properly or find the low SWR points on some or all band are outside the amateur bands you will need to remove the heat shrink covering the trap inductors. Water collects in them and simply wont go away untill you remove the heat shrink. I did this to an R-5 I had and it work great after that. Don't worry about replacing the heat shrink covering the trap inductors. I left my R-5 up for years without anymore problems without the inductors covered.

Andy,
You want any discone that covers from 50 MHZ to 1300 MHZ. In other words; any one that has a vertical radiating element at a 90 degree angle to the main horizontal radials. It's really nothing more than a short loaded whip but it will increase your tx pleasure. Don't think of putting more than 100 watts into it though or you may burn out the loading coil.

Chris, I don't know the call(s), but Max Busek (Now deceased) had two sons, also hams, who were involved with him at Madison Electronics in Houston, Texas. This was quite a number of years ago. It's my recall that Max had one of these TelRex antennas. I seem to recall actually seeing it at the family place out in the west side of Houston just before or after Max died. If you have access to a call book lookup program, you might look up that last name and see it it matches anyone still in Houston. Memory says that one son was named Don Busek.

The family crew did a substantial amount of work with TelRex and the product line all those years ago. I bet Don Busek can give you a lot of data on the antenna. Memory, very foggy, says that one of the weak points in the beam was an insulation problem somewhere in the system which they had to overcome. The family was darned resourceful and machine shop work and so on was easily in their style of approaching problems if they needed it.

Just a lead, you can run it down if you like.

And if the far end isn't terminated, it's not a traveling wave antenna.

The defining characteristic of a traveling wave antenna is that there
are no standing waves (reflections) on the antenna. The only way to
achieve this is to terminate the far end of the antenna, or have an
antenna of sufficient length that an appreciable portion of the power on
the antenna radiates before it reaches the far end.

If the far end is terminated, but the antenna isn't several wavelengths
long, most of your power will be wasted in the termination.

Gray

914. PVC Dipole Center Designs

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-09 03:59:55 UTC
From: kr2v@aol.com
Message-ID: <20010108225955.29484.00000915@ng-cs1.aol.com>
Source record: 172489

Greetings:

I'm looking for design ideas to home-brew dipole center insulators. I know there's not much to it, just looking for some ideas (PVC parts, etc.) that work well together.

Thanks,
Joe - KR2V

Nope, he just said, "It is interesting to note ..." and also
talked about the short term effects of rain.

Myself, I usually use a strip of thick circuit board material with all
the copper peeled off. I drill a hole on the center for a SO-239 coax
connector, and I drill a hole in each end to hook the wires to. The
antenna wires are run through the holes and looped back into a knot.
Then I run a wire from the coax connectors to each leg of the dipole.
This way there is no stress on the coax connector. Solder all the
connections. Also I drill a hole above the coax connector to hang from
whatever support. With this type of insulator, I use a coax choke for a
balun. There are many other ways, but I like using the so-239 so I can
plug whatever coax I want. MK

Joe,
A sheet of plexiglas, few SO-239's, 1/2" hole drill bit
and a skill saw = thousands of center insulators.
'Doc
PS - (well, hundreds anyway...)

I have the small hf RF-1 and like it very much. The only downside to it, and that is only a nuisance, is that tuning precise freqs in the digital window is "jumpy". but, you can readily get close enough, if not right on the mark.

919. Re: Travelling wave HF vertical help ?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-09 04:54:17 UTC

Source record: 172494

The Bushcomm antennas do appear to have a load, which probably qualifies
them as traveling wave antennas. But they are not terribly long
electrically, so the load is going to waste most of your transmitter
power. But the match will be good!

If efficiency isn't a major concern, you could probably make a
satisfactory vertical TWA by suspending a piece of coax vertically.
Feed the inner conductor against a ground system. At the top tie the
inner to the outer. At the bottom tie the outer to ground through a resistor.

Chris, I had one at my contest station for 10 years between 1976 and 1986. At 150 feet it survived several near misses with FL hurricanes. I gave the antenna to W3AU when I took the station down and I believe he still has it in use. I had the blueprints for it until only a few months ago when I finally discarded them. Believe that Ed may still have a copy.

It worked with zero problems for the 10 years, no arc-overs with some pretty good sized amplifiers through rain and shine. I never modified anything on it, had other antennas for other bands. Took the skill out of working the world on 40 meters.

921. Re: Radials over salt water?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-09 05:28:43 UTC
From: Richard Karlquist <rick@area.com>
Message-ID: <fkx66.103025$A06.3560669@news1.frmt1.sfba.home.com>
Source record: 172496

I haven't tested radials over salt water, but I have tested them over my 230 foot diameter ground screen. The ground screen has wires running north-south and east-west on 3 foot centers, with all the crossovers soldered. On 40 meters, I did ground wave far field signal strength tests with a vertical and found that was no difference in signal strength between a few elevated radials and 120 half wave radials whose ends were soldered into the ground screen. The number of radials did however affect the driving point impedance. As W8JI indicated in another thread, driving point impedance is very misleading as an indicator of antenna performance.

I believe N6BT when he says you only need 2 or 4 elevated radials over salt water and you're all set.

Rick Karlquist N6RK

Works for me! NJ7P beat you to it, though.

Used RCA tube manuals are still pretty reasonable. One guy scanned his RC-10 (the first real RCA receiving tube manual) and you can see it at:

http://www.nmr.mgh.harvard.edu/~reese/RC10/

--

You probably already know this, but Loren Windom, 8GZ-W8GZ, inventor of the antenna that bears his name (see the article "Ethereal Adornments" in QST, about 1927), was a QRP buff. Worked Australia with but a few milliwatts back in the twenties.

73 de Jim, N2EY

923. Re: What is NOAA ?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-09 05:35:09 UTC

N ational O ceanic and A tmospheric A dministration.
Its acronym is a pun which makes it a pretty good nmemonic device
for the agency's function.
NOAA is pronounced the same way as the name of the NOAH in the bible
story who warned the people about the coming 40 days and 40 nights of
rain and flood.
NOAA's task is to predict the weather and to warn people about impending
severe weather.

Asunto: Net-abuse from your user PHIL DRAGOMAN

##
For the Attention of the Net-Abuse Service.
##

The user Phil Dragoman (Road Runner) is commiting net-abuse again and
infringing the Acceptable Use Policy for AT&T Road Runner Newsgroups.

He keeps sending libellous, sexual, offensive and racist Usenet posts.

Please find enclosed his last offensive posts (these posts are about
fucking the mother and father of Spanish citizens, and he use to employ
terms like: whore mother, asshole, bitch, fuck, etc. This is a sample of his
Usenet post using Road Runner:

Phil Dragoman <phil.dragoman@literally.com> escribi&#65533; en el mensaje de
noticias 6kv26.21303$1M.4882122@typhoon.ne.mediaone.net...
>Vete tomar por el culo, tu hijo de la chingada. Chupa la polla de tu
> padre. Vete darle el beso negro a tu madre, t&#65533; mula. T&#65533; cobarde
> sin pelotas. Perro sin honor. Mr. Nobody.
>
> Phil
>

The translation into English is:
"Put it up your rear end, you son of an indecent woman. Perform fellatio
with your father. Lick your mother's anus, you she-mule. You are a coward
without testicles. Dishonourable dog."

Another post attached below says:

Phil Dragoman wrote: CHINGA TU PUTA MADRE
(Translation into English: FUCK YOUR WHORE MOTHER)

Yet another post attached below against a Spanish citizen below says:

>Phil Dragoman wrote: "Ahora puedes hacerse puta tu mismo. Viene de
familia, &#65533;no?"

Translation into English: You can become a whore now, since all the women of
your family are whores.

##
I have informed of this NET-ABUSE
against Spanish Citizens to the Spanish Government
and to the Spanish Authorities.
##

Please, take the proper action against this deranged user, he use to call
himself a "former politician" in his posts to Usenet.

Regards,

RAC
SPAIN

When over salt water NO radials are necessary. All that's needed is a small
ground plate immersed just under the surface.

This is going to sound dumb, but here goes anyway. Are the radials supposed to be connected to the base of a vertical antenna, or do they just radiate out from around the base, but are not actually physically connected? Its hard to tell from a schematic diagram. Sometimes it looks as if they are not actually connected to the base of the antenna. If the radial system were to be connected to the base of the vertical, and if one were to make a homebrew vertical antenna fed with coax, would one solder the shield to the radial system, and the center connector to the vertical portion of the antenna? That seems like a short to me.

I disagree.

Measurement of driving point impedance of a vertical antenna is the most
informative indication of efficiency and performance which can be made.

Do you know of any other on-site measurements which will tell you more ?

"J",
The vertical part of the antenna is connected to the
center conductor of the coax, the radials to the braid.
The radials are physically at the 'base' of the antenna,
but insulated from it.
'Doc

> That seems like a short to me.

In a normal series-fed vertical, the most common variety, the base
of the antenna is insulated from the ground system. The radials are
connected to the shield of the coaxial feedline, and (assuming that
direct coax feed is used) the center conductor of the feedline is
connected to the lowest point of the vertical element.

There are other methods, such as slant-wire shunt feed and the
folded unipole (in which the element is grounded and fed at an
elevated tap point), and often antenna couplers are used at the base
of the vertical, but what I have sketched out is the most basic
arrangement possible.

With all good wishes,

Kevin, WB4AIO.

Gentlemen, there is an easy way that can settle this, both of you find a neutral arbitration body (like a computer lab in a university possibly).

Mr Lewallen, you send the alledged "pirated" file to the lab and Mr Cohen send the file of which you are copyright holder to the lab also.

Get the IT staff at the lab to make a bit for bit comparison on the files, if they are different there is no case (possible case for Mr Lewallen). If there are identical binary patterns in the file there is a posibility the file has been copied and modified(thus a case for Mr Cohen), any good it lab can do this.

Once the results have been verified you can both settle this away from the NG

easy uh!

Kev

PS. I'm as sick of this as the next man and I just wish we could get back to antennas :), Happy & Prosperous new year to you all.

>
> Rick Karlquist N6RK

All this talk is starting to lead me to believe the "theoretical gains"
of adding radials may be over stated for areas of good ground, and
understated for areas of poor ground. Note that at Tom's QTH he saw
about a 10 db increase in comparing 2 radials to 60. He states many see
this increase, but some do not. So I assume the ones that do not are
sitting on fairly conductive ground. Being most are not on very good
ground, they are seeing the large differences. In my case I have an inv
L that I can compare to my low dipole. I only have 2 1/4 wl radials and
and about 5 short ones at this time. And to dx, my inv L is winning over
the dipole. Now, I know for a fact that the ground conditions here are
better than most. Probably better than 75% of the rest of the country.
So with my few radials and the decent ground I do seem to be working ok.
But more radials would still improve a good bit, I'm almost sure. The
reason I know this is I've compared a 40m 1/4 wl vertical ground mounted
with 32 radials, against the same antenna at 36 ft with 4 sloping
elevated radials. Both over the same "decent" ground. Being as 4 radials
at 1/4 wl up, are appx equal to 50-60 at ground level, I know about what
it should do. Pretty accurately. If the ground here was really good , as
in close to sea water cdx, I should have seen the same appx performance
from both antennas, or close anyway. The results? The elevated antenna
was way better than the ground mount version. Night-day difference
really. So that could show that even with my "fairly good" ground, I
still need radials for optimum performance. As you get near sea water, I
could see where 4 radials could do well. They would be one of the "other
guys" that Tom referred to that didn't see much difference. I'm myself
in that category a bit. I can run a inv-l on 160 with no radials and get
out. But I've never confused myself to thinking adding radials won't

help what I have. I'm not over sea water. MK

OK so far.

> That requires an armed forces, a police
> system, and a court system.

That's all? No executive branch beyond the armed forces and police? Who determines when the armed forces fight and who they fight? Who negotiates with foreign governments?

What about the legislative branch? You don't mention them at all. Who determines what the power of the police and courts are? Who makes the laws for the police and courts to enforce?

As is typical of simplistic political systems like libertarianism, the hard details are glossed over.

> Those are the rights I want and I'm willing to
> pay my fair share for those services.

Collected by whom? And who determines what your fair share is?

>What I object to, for instance, is
> using the money I paid in taxes to finance partial birth abortions.

I see. You want the rights but not the financial responsibilities. Just like I said. How many abortions are paid for with tax dollars?

Hi Kev,

Your solution is dead-on and certain - there is at least one problem.

Before Steve Best revealed his version of the MI2, there was NO
publically available copy circulating to be pirated. Hence there was
no way to infringe on a document not already public (it may have been
privately circulated, but absolutely no one has claimed that status
except myself and I have not circulated it).

Another problem lies in your method above. If those two copies were
submitted (from the presumed, "offended author" and from Steve Best)
and found to be identical, then it must be the "offended author" that
is the one who is in actual violation of copyright. Why do I say
this? Because I have copies of both and THEY DO NOT MATCH. With this
knowledge already apparent to the "offended author," it is more than
obvious that no comparison will be made. With no comparison made
(outside of my own), there can be no forward movement to resolution -
hence the lack of closure (and the continuous cat-calls from the
"offended author").

These issues were warned against by myself long ago, Kev. There will
be no further movement and given the nature of recent outrageous
claims by that "offended author" (this thread title is a glaring
example), there is unlikely to be any further discussion beyond

trotting out the old claims. You (we) will be treated to repetition, but no revelations.

One solution (that is, positive forward movement) will be coming from Steve Best in the form of his published study of his designs and the much weaker player MI2. Steve has in the past disclosed more than half a dozen designs that whipped the best offered from this "offended author;" giving good reason for offense (but only in the competition of scientific challenge). Having browsed the copy, it gives me every impression that there will be one more serious player in the discussion of fractals to replace the intellectual void. The first lesson Steve may hope to pass along is that the "Fractal" form has little to do with the claims that have been ascribed to it. This, of course, could be considered to be very "offensive," but only to a very defensive and weak proponent of those claims.

The last issue of this folderol is:
Where did the $1000 go for this unregistered Lottery (the so-called "Challenge")? Does the state of Mass. regard such activity as benign?

I use 14 ga. wire on my groundplane but I don't think it's too important whether it's 12 or 16 ga. (assuming you are running 100 watts). Be advised, though, that the end of the radial will be electrically hot so it should be where nobody can touch it.

Kevin,

There is nothing to be settled in terms of the authorship of
the file. When a lawsuit is finally brought - if ever - then and
only then will there be an issue requiring investigation.
You've been suckered in by the constant bullshit emanating
from an apparently psychotic party.

What people don't seem to realize is that said party seems
more interested in stirring up controversy than anything else,
and will stoop to whatever means that party finds necessary.
The simple answer is to totally - and I mean TOTALLY ignore
ANYTHING that party posts. Sometimes, a posting from that
party seems legitimate. But we often find the thread degrades,
due to that party's further posts, into the crap we find here.
I do not think that reasonable conversation with that party is
possible.

I leave it to you and others to determine to whom the phrase
"that party" applies.

Tom,

Heard you on the air in around 1 am EST today (01/09) with S6??? (maybe EAG?) (I wish I wrote it down). The frequency was 35?? (3515?) I just caught the tail end of your QSO. You not only have good antennas and good comments here, you have a good fist!

RG-6 is pretty standard for TV signal distribution within a home.
There are differences in brands of RG-6-type cables, but without some
instruments it will be difficult to evaluate them. "Anecdotal
evidence" (personal cudos or horror stories) are probably worth
something. But with an amplifier mounted near the antenna, I'd expect
performance to be dominated by the amplifier rather than by the cable,
unless it's really bad cable. It's unlikely you'd notice a difference
in a home TV distribution system between single-shielded and
multi-shielded...the inherent symmetry of coaxial cable makes external
fields quite low for either. It's maybe more important to worry about
how long the coax will last when exposed to whatever environment it's
going to see, espeically if part of the run will be built into a wall
where it's not easy to replace.

Cheers,
Tom

I am organising a Portland on the air weekend and would like to hear
from interested parties from all "Portland's" around the world. I know that
there are quite a few in North America so please get in touch if interested
so I can organising. I live on the Isle of Portland in Dorset, England and
think it
would be a good event to get us all on air for a weekend friendly contest
with certificates for working all of them etc. If you or your club are
interested
please let me know the best dates during the summer and I will set a date
soon.

Hi Tom,

That "should" be true, but I have very ordinary results that confound that expectation. That is, due to cable leakage (going in, not coming out). I often encounter visual beat signals for local over the air transmissions (channels 5, 9 and 11 here in Seattle as you may well know) that mix with the video feed. The mixing is obvious in that the stronger cable signal is always much later in the scan than the ghost that over-rides it (much later being roughly 10 scan lines or roughly 0.5 mS). The channel 5 over the air signal, combined with the cable feed, is enough to drive my AGC into saturation. Now, given that AT&T laid new cable to my feed point, it is undoubtedly the Radio Shack line that I've used here at home that is the inferior component. My solution for these channels is to simply remove the cable feed and allow the short coax to the TV to pick up the signal over the air.

>
> Thanks in advance.

As you can tell from all the answers you are getting, there are a lot of things that work even in apartments. I had a 4 element quad AND rotor on some short pieces of pvc pipe stuck in a Christmas tree stand that I could just move on and off the balcony when needed. I was able to work simplex all over central Florida (and beyond quite a few times as well) with no problem on just 25 watts.
Just use your imagination and you will be pleasantly surprised at all the things that can work.

What the heck are you talking about, Cecil?

None of the NALs I looked at mentioned how the jamming was done. Many
were for obscenity/profanity, not jamming.

How does anyone know what is being used at the jamming transmitter
unless they are at the transmitter location?

The challenge was:

"Point us to an NAL in the past ten years where the FCC says a ham was
jamming or doing obscenity/profanity using Morse."

Not "using a morse code key" but USING MORSE. None of your typical
weasel-wording and mealy-mouthing will get you out of the basic fact
that you can't find an NAL to answer my challenge.

If a person bops another on the head using a Morse code key, does that
mean an assault was committed with Morse code? Of course not.

But not Morse. Which means the mode DOES influence behavior. Which is
exactly what I claimed. Thanks for the confirmation.

While I agree absolutely with those who have recommended a preamp at the antenna and 'pretty lossy' coax, be aware that such preamps are prone to overloading from amateur transmissions. Those covering nominally 'DC to blue light' (eg 50 to 860MHz) may be affected even by 160m transmissions. Some front-end filtering, shielding of the preamp, and filtering of the power feed may be necessary.

If you scrounge some low-loss coax from you local friendly cable company, save it for transmitting! (Even if it is 75 ohms).

Ian.

954. Help: Alarm system RFI

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-09 22:37:43 UTC
From: Robert Fanfant <fanfant@ix.netcom.com>
Message-ID: <3a5b92b8@news.microsoft.com>
Source record: 172425

A neighbor is asking for advice about how to cure RFI that is getting into his alarm system when I'm on the air. When I'm on the air, both his alarm keypad(s) LEDs start to flicker, sometimes causing his alarm system to "turn on".

I"ve ordered some torriods from Amidon (FT-240-77). Will ask him to install as close to the keypads as possible. Does he need to install the torriods on the keypad inputs at the alarm system also?

Any other suggestions?

No, but I think it likely that a person who uses a Morse key to bop someone on the head probably also uses it to send Morse code. Do you think that the jammers who send a series of dits with a keyer bought the keyer just to send a series of dits?

> But not Morse. Which means the mode DOES influence behavior. Which is
> exactly what I claimed. Thanks for the confirmation.

I don't think you are quite confirmed yet, Jim. The fact that hams who would violate FCC rules don't generally do so using sent Morse code simply means that they find other forms of operating (from continuous waves to dits to voice) more convenient or enjoyable (?) to use to wreak havoc. If you want confirmation, analyze the percentage of hams who are given NALs that have also passed a code test. *IF* any correlation exists, it should be apparent there.

Technical know-how is still a valid mandate of the ARS as per part 97.
The technical know-how is not a communications mode, a language, or a
Holy Grail of radiotelegraphers world-wide. Technical know-how is one
of our reasons to exist -- CW isn't. It is non sequitur to substitute as
yu suggested.

How close? 1kHz? 5kHz? 10kHz? How big is the jitter? My application
requires step measurements at 5kHz intervals with +/- 500Hz. +/- 1kHz
acceptable, as I have an external frequency counter I can use.

Choke the hell out of all of the leads coming into the master processing unit (both alarm leads and power). Most alarm installations use unshielded cables so they are really big antennas given the lengths.

Make sure all of the cables do multiple wraps around "donought" shape chokes. I used the ones from palomar engineering. They have an interesting one that clamps together with plastic shell. Radio Shack sells the same one but for a higher price.

Also, make sure the ground is connected. Many installers skip this step because the alarm box is usually not easily grounded.

Hi Kevin--

Most amateur radio service tranceivers are preset for 5-kHz peak deviation at the factory. Commercial radio service transceivers, on the other hand, may be set lower---say 2-3 kHz--to reduce the potential for adjacent channel interference in congested high signal areas. If a commercial repeater is involved in the link, 5-kHz of robust modulation could easily bust out of the receiver's passband and cause your signal to sound distorted--or to cut out on peaks. As a practical matter, you transceiver's audio must conform to prevailing practices on the channel of interest, or your radio may sound like horse poopie to other users!

Moreover, communication law dictates we avoid using non-FCC type-accepted radios on ANY commercial circuit--even if we're otherwise authorized to use the channel and have "numbers" becuase of our occupation. It's no secret that some off-duty cops, fire, public works, boaters, and paramedics use opened up ham rigs to communicate because they make really affordable back-up radios! But its not legal!

Best advice? Get a cell phone!

I had this problem on mostly 80 meters with 100 watts.

I installed a 100uh choke AND a .01 disc capacitor on EVERY lead into
the panel.

one of the keypads would beep I used three or four turns around a radio
shack torrid at the keypad.

I am now running 1500Watts no problem.

Richard,

In a practical sense this is not a problem, or at least is a problem
that will fix itself. I also note that you are assuming you have
knowledge of the material whose copyright is claimed to have been
infringed, but there is no need to make this assumption.

Before a copyright infringement suit can be initiated (and, in fact,
before it makes sense to send letters informing of the infringement)
the copyright on the material in question needs to be registered,
with a copy of the material thus being deposited with the Library
of Congress. When this happens you will know exactly what the
material is of which infringement is claimed, and can make any
comparisons you want. Until this happens it doesn't matter, since
there can be no suit for copyright infringement of unregistered
material.

Copyright registrations are included in the catalog accessible
at http://www.loc.gov/copyright/. Other than a Fractal Antenna Systems
logo, I can't find anything even remotely related to the topic at hand.
Without the copyright registration this is all much ado about nothing.

I have two modded FT-50's, had good audio reports everywhere. Works fine with the kid's FRS radios, get good signal reports on local repeaters. Maybe just something wrong with that unit....as far as power output goes, I assume it's pretty close to in-band, as it seems to have comparable transmit capability to my commercial HT's.

Source record: 172447

When I first moved to Sydney I had to live in an apartment so came up with a multiband antenna that worked well.

Get 2 extendable antenna's (transistor radio aerials), mount them onto a piece on insulation and feed with coax. Adjust the antenna lengths for the band you want to use, I could get 50/144 and 432 from the antenna 's that I used (55ins long fully extended).

The assembly clamps to the balcony to get good outside radiation and can be either vertical or horizontal depending what you want to work.

Hope this helps

I found the "coarse" tuning far too fast, and the "fine" tuning far too narrow in range. Unless you have the fingers of a safebreaker, the Autek won't meet your requirements.

Maybe, Ed. But that's not the point at all. The claim was that Morse was used
for jamming, which has not been proven at all.

> Do you think that the
>jammers who send a series of dits with a keyer bought the keyer just to send
>a series of dits?

Could be. How do you even know a keyer was used unless you are at the jamming
site?

One of the NALs cited a fellow who transmitted RTTY on top of another ham's
transmission. But no mentions of Morse at all.

Show us the NALs.
>
>> But not Morse. Which means the mode DOES influence behavior. Which is
>> exactly what I claimed. Thanks for the confirmation.
>
>I don't think you are quite confirmed yet, Jim.

I'm definitely not disproven, either.

> The fact that hams who
>would violate FCC rules don't generally do so using sent Morse code

"Don't GENERALLY do so?" Nonsense. They are so rare that NO NALs have been
issued by the FCC for such use of Morse. None. Not any at all.

I'm not saying it never happens. But compare ZERO to the number of NALs in any
of the enforcement logs.

> simply
>means that they find other forms of operating (from continuous waves to
>dits to voice) more convenient or enjoyable (?) to use to wreak havoc.

And what mode are they interfering with? Who are they jamming?

How about the profanity and obscenity? Were they spelled out in Morse or spoken?

Where are the NALs?

> If
>you want confirmation, analyze the percentage of hams who are given NALs
>that have also passed a code test. *IF* any correlation exists, it should
>be apparent there.
>
Nope. That's not logical. You taking reasoning lessons from Cecil? ;-)

The point is not the TEST at all. Code testing is essentially a dead issue. FCC has dropped it to its bare minimum, and only the treaty is keeping it alive. If the treaty goes in 2003, kiss any US code testing goodbye. Not because of anything hams or ham groups say, do or want, either. FCC wants a simpler life, that's all.

The fact that somebody has a non-Tech ticket simply proves that once upon a time they managed to pass a code test. Might have been decades ago. Says nothing about their current level. And the same goes for the written tests.

My point is that violations WHILE USING MORSE on the ham bands are so rare that they are off the FCC's radar. Just not a problem. Even though Morse is the second most popular HF mode in ham radio.

It's the USE, not the TEST, that I'm talking about. And so far I've seen nothing to disprove or even challenge my assertions.

But it's electro-politically incorrect to point out any advantages of Morse to some people. Not you, Ed, of course, but there are some folks who deny ANY good thing said about the mode.

I was fixated on "end of the radial will be electrically hot." Is the whole
radial electrically hot? And if insulated the end may be the only part
exposed to the touch? I am new to this.

>
> --steve

Hi Steve,

I read all the other answers to your query, but I am wondering if you really are asking for "trap" design or simply "loading coil design". If you are only interested in shortening a single band dipole you can do all the calculations with a program called HamCalc.

There is a program in HamCalc that allow you to enter the space available and it will calculate the value of the loading coil. It also give you an idea of efficiency since you are no longer operating at the preferred lengths.

Once you know the value of the loading coil, you can use another HamCalc program to determine the "# of turns, diameter of insulator, length of conductor around the insulator, etc..". It's a nice program and runs on just about any PC.

Check out:

http://people.delphi.com/slott/ham/index.html

For a good description of HamCalc and it's contents.

I agree that the coarse frequency control is too sensitive. I've replaced the original knob with a small vernier control that I picked up at a hamfest. It helps considerably.

I also have had problems with erratic, erroneous read-outs. I believe, but have not confirmed, that the problem is the connection of the coax connector to the PC board. There have been several other reports that the connector-PCB integrity is a chronic problem with the RF-1.

Ed Hare wrote:
"Do you think that the jammers who send a series of dits with a keyer bought a keyer just to send a series of dits?"

Jammers jam to disrupt and to demonstrate their power to do so.

Some jammers insert their own message to the audience on the channel. Jammers may want to be known, but not necessarily accessible. Jammers may want to remain unknown, or they may not care if they are identified.

CW is less able to cover up a channel than modulation. A series of dits might be offensive enough to evict channel users. Voice may be more insulting or otherwise offensive. All sorts of noise has been tried.

Jamming has become a science as well as an art. In the wars, hot and cold, jamming has been a tool to affect communications and information. Modulation has been thought the best way to jam.

Best regards, Richard Harrison, KB5WZI

So, can you give some examples of the unique words (nouns, verbs, adverbs
and adjectives), grammar, and syntax of this Morse language? I can give such
examples for actual languages such as English, German, Spanish, Russian,
etc, but not for "Morse language". That's because Morse isn't a language, of
course. It doesn't have its own words, grammar, and syntax independent of the
message texts being sent via Morse encoding.

The texts that you send via Morse encodings *do* have those attributes
of language, however, because the texts are in a real language, IE English,
Spanish, French, etc. Encoding them via Morse for transmission doesn't

translate those texts to a different language. They are still English, Spanish, French, German, Russian, etc language texts that just happen to be encoded for transmission with Morse characters instead of ASCII characters, or Baudot characters, or printed font characters on paper or on a computer screen.

No matter how proficient a Morse operator is in decoding Morse, he still won't understand the message text unless he understands the language in which it was composed. If Morse were an actual language, then he would understand what was being sent, because it would have been translated to a language (Morse) with which he is fluent. But it doesn't work that way because Morse isn't a language. It is merely an alphabetic encoding, no different in principle from ASCII or Baudot. The messages are still in their native languages.

This can easily be confusing to a monolingual person. He is so used to thinking in only one language that he may not even realize what language is. To someone fluent in several languages, however, the distinction between language and the means used to convey it is quite clear.

Language doesn't have to be aural, of course. It can be written or signed or represented in some other way. Nor does it have to be a natural human language. For example, computer languages are languages because they have their own words, their own grammar, and their own syntax. Mathematics can be a language too. It has its own symbolic equivalents of words (variables and constants), its own rules of grammar (2+2=4), its own syntactic forms (equations), etc. Like conventional natural languages, these artificial constructs are also languages which convey meaning to those who understand them. But the ASCII often used to *spell* the words of these languages to a computer is not a language. Neither is Morse.

The ITU correctly calls it a "telegraphic alphabet". We can use that telegraphic alphabet to convey messages in any language which can be spelled by that alphabet. But those messages are still in their native languages, not in a separate Morse language.

Now the Q signals, and certain other abbreviations that are in common use by radio operators, are a sort of very limited pidgeon language. But these aren't part of Morse, and should not be mistaken for Morse simply because radio operators commonly convey them via Morse. They convey the same meaning if transmitted via ASCII, Baudot, etc. They are independent of the encoding system used to convey them.

That's true of any real language. An example is that this entire message has been conveyed to you via ASCII encoding, but it isn't an ASCII language message. It is still English, regardless of the transmission coding used to deliver it to you. If I'd laborously keyed it in Morse, it would still be English language text, not Morse language text. Someone not fluent in the English language still wouldn't know what it says, *no matter how good a Morse operator he might be*.

But if I'd translated it into *another language*, for example German, then anyone fluent in German would understand the message. If Morse actually were a language, then translating the message into Morse would make it understandable

by anyone fluent in Morse, whether they knew English or not. But of course that isn't true, because Morse isn't a language.

As Roy says, wire loss is usually not a dominant factor.
A test: run program with no loss, then one metal, then the other. Look at gain and loss or efficieny. If there is much difference, try a redesign or break the antenna into elements and try to fing the lighest loss, and redisign that element.
A tenth of a Db is probably the accuracy of NEC, so don't worry about small losses.

Source record: 172462

A common way of generating ground loops is to use multiple ground points to a metal chassis. Many times this is OK since the chassis is a low impedance circuit element. However, if there is a high current between one pair of grounds, and there is another pair in the high current area which is sensitive to small voltages, with a relation between the sensitive and high current, there will be feedback. The inate pervisity principle states that the feedback will always be damaging (confirmed by experience!). Power Amplifiers, in particular, can oscillate when fed a little signa l, develop a parasitic, or even destroy the tubes/transistors.

The cures are: use a single ground point:; make the chassis very low resistance; keep high current grounds away from low voltage input points; use toothed lockwashers or direct solder to the ground, & some others.

Grounding is an art: it helps to keep your fingers crossed, or other protective actions. And to expect a problem with a new design.

I absolutely agree. Concepts like SWR and transmission line loss aren't
really that difficult to understand, but one has to be willing to put
in the time and effort to really get a handle on what it means and all
the implications.

> By that I mean the ability to strip a question or a

Yup. Thoreau went to Walden Pond for exactly that reason in another
area of thought. He was willing to put in the time and effort. Your use
of the phrase "strip a question or a problem down to its most basic and
simple ideas" really fits.

Same here. Most of the work we do is actually simplifications and
specializations of those four equations.

Agreed. Look at what happened to Armstrong and Farnsworth.

Technical writing is among the most difficult because the author must
function on several levels at once. He/she must both have the knowledge
to be passed to the reader, and yet imagine being the reader who does
not have the knowledge.

One of the main functions of books like the ARRL ones is to bridge that
gap, using the most basic (but accurate) writing possible.

One of the best examples of good writing of this type is found in the ARRL Antenna Books, explaining the Smith Chart. I don't know if they still use the explanation I'm referring to - I first saw it in an edition from the early '70s. Takes the reader through the whole process without bogging down.

Yup. Or NR5Q, Bruce Vaughn

Main problem is that to build up that basic knowledge requires the time and willingness to do the "simple" stuff first. Like wading through the dipoles and 8JKs first and really understanding them.
>
> > math and science skills of much of the US

Yep. The example speaks the loudest though, but it's the hardest to change. When a newbie visits a shack or FD site and sees nothing but expensive manufactured antennas and rigs, it says volumes about those using them.
>

As already posted nolox will work. I wouldn't put it back together
without it. The protective name really should be changed to
protective/conductive. It really helps avoid bad connections in the
element junctions. Without it, you start to build up that nasty grey
corrosion and start getting bad connections. Usually will see the swr go
south, and then when you crank alot of rf into it, it will fix it for a
little while. I've had this problem on verticals many times when I
didn't use paste or connecting hardware. It takes quite a while to build
up, but when it does, it will drive you crazy, and you'll have to pull
the beam to fix it. Not worth the work for the fairly cheap price of the
paste. MK

Sure it matters. You haven't responded to my challenge because you
can't.

> Morse code tested hams
> use their Morse code keys to jam other hams.

That doesn't mean they were using Morse. You just want to badmouth the
mode.

>I have heard it.

But have you SEEN it? If not, how do you KNOW they were using "Morse
code keys"? A simple 555 circuit will generate a pulse train for such
purposes. Computer software can do the same. A tape recording played
into a mike will do as well.

If someone uses a microphone to drive nails, it doesn't mean they
were "using voice".

Point us to the NALs. Otherwise you're just blowing smoke and
badmouthing.

Hi Dennis,

Your assessment of the need for registration is certainly an alternative, but it is not a necessity for the author who wishes to pursue violators. Copyright exists from the moment of completion, not through the act of appending a c enclosed in a circle or with the notice of copyright and a year date. There is certainly more protection through registration.

As for your statement:
> I also note that you are assuming you have
>knowledge of the material whose copyright is claimed to have been
>infringed, but there is no need to make this assumption.
This is not an assumption. I do in FACT have a copy of MI2 direct from the author, not indirect through a third party or through myself cloaked in the appearance of a third party to the author. The author presented this file to me, I did not seek it - except to show interest to the offer.

The two files have no points with which they agree in totality. The two files have no points in which they agree in description - they are simply similar and this is not a basis of copyright infringement. You cannot copyright an idea, that is the provence of patent. I have my own MI2 which is different from these two and it too reveals no particular gain or loss in the quality to the process of evaluating the form.

The last compelling blow to the logic of copyright infringement is found in the author's own announcement to copy and test and to respond in kind with an improved design or better design. Steve Best took up that challenge and demonstrated that the MI2 is NOT a particularly good example of the best characteristics for the given physical limitations made in the challenge.

The last, last compelling blow to the logic of copyright infringement is found in the author's complaint of it without pursuit. The law does not allow you to sit idly by without penalty. There is a particular term for this in patent law (which escapes me at the moment), and the gist of it is that if you do not pursue your rights, you cannot complain or recover for that period that you abandoned to your obvious indifference. (All may note the complete silence that now attends these issues.)

There is NO ONE here that will suffer any consequence but nuisance.

I will amend that last statement to point out that there may be one in this party to suffer for running an illegal Lottery - hope this helps.

... and an antenna that floats up and down with the tide?

What N6BT actually said was that you only need 2 or 4 elevated radials over the *beach*. That stabilizes the performance as the tide goes in and out.

Radials laid *on* the beach were notably poorer, which is not surprising because the conductivity could vary anywhere between that of dry sand and salt water.

In light of the posts that W8JI-Tom has made here on the subject, do you really think it's leakage from single shielded coax, or some other cause? In any event, for a home antenna distribution system...will it make any practical difference if there is -40dB vs -200dB of leakage from the line?

Cheers,
Tom

Keith,
We (Elk Antennas) make a small, (24 inch boom) 5 element log periodic
for 2M
has good gain (measured by others at 6 dBd) 20 dB front to back ratio,
light weight 1.4 pounds, great for attic, RVing, backpacking, fox
hunting, great all round gen purpose antenna. We also make LPs for 220
and 440 bands plus specials for ATV.
If interested, e-mail and I'll send SWR,directivity plots plus photos.

Best wishes and happy new year from ray, w6fya

chris,
I have a copy of John Kraus' book second edition "ANTENNAS" on pages 453 through 458 he writes about six different W8JK close spaced antennas and gives lots of info, showing effects of spacing and phasing. He talks about the article that gave him the idea for his antennas and how the designs evolved.

I'm sure there are articles in QST regarding this antenna type and there must be references in some issues of the ARRL antenna handbook.

You should be able to find one of his books in your local library, but if not there in a local university library. You should be able to put in a request to borrow a copy through your local library.

Let me know if you encounter any difficulty, I'll do a bit more searching.

Best wishes from ray, w6fya for Elk Antennas

Gary Coffman wrote:

> So, can you give some examples of the unique words (nouns, verbs, adverbs
> and adjectives), grammar, and syntax of this Morse language?

Yes. Any combination of Morse sounds that strike your eardrum and directly create an idea without the need for translation. A good morse op does not hear characters, he hears ideas. He uses whichever written language he knows if he writes those ideas down, or whichever spoken language he knows, if he speaks those ideas.

Unique words are not required for something to be a language. I am sure you would agree that French, Italian, Chinese, English etc are all languages. Each uses different words to express the same ideas. Morse words are sounds in a particular combination. The difference is fluency. When you are first learning any language, it is hard, and you struggle to grasp the idea behind the particular set of sounds associated with the idea. When learning a second language, you struggle to translate it into your native tongue. But when you become fluent in a language, you no longer struggle and you no longer translate. You "think in" that language. You don't even need fluency in morse to see that beginning to happen. Some sets of sounds - for example the sounds that make CQ, test, the, hihi come to mind are probably those where morse fluency starts. After hearing those sounds enough, they no longer appear mentally as distinct letters they become words, then concepts.

In Mexico at the airport in Merida back in the early 70's, I spoke with the radio operator there while he was working. He cocked one earphone off while we spoke, ran a bug with his right hand and typed with his left. And we spoke in English and in Spanish. He did not miss a beat - was copying and sending at 50 wpm. He told me that he had to read what he typed to know what he heard. The process for him was automatic - what came in his ear went onto the paper without conscious effort. (He used only a couple of letters, and the rest were numbers. He told me he was receiving information on windspeed and direction at various altitudes from other airports. I did not ask what he was transmitting - I assume it was the same info for the Merida location, being sent to other airports.)

Spoken language simply "encodes" ideas into sounds. Morse is no different - it is a means of "encoding" ideas into sounds. In the beginning use, we do translate those sounds into whatever language we know - but with fluency, no translation is necessary. That man in Merida

actually "thought in Morse".

> I can give such
> examples for actual languages such as English, German, Spanish, Russian,
> etc, but not for "Morse language". That's because Morse isn't a language, of
> course.

And your "of course" is simply wrong.

Richard,

I don't think your first sentence is correct. You certainly have
copyright from the moment a work is completed, but you need to register
the copyright before you can take action against violators. Here is the
wording from U.S.C. 17.411:

(a) Except for an action brought for a violation of the rights of
the author under section 106A(a), and subject to the provisions of
subsection (b), no action for infringement of the copyright in any
United States work shall be instituted until registration of the
copyright claim has been made in accordance with this title.

This is pretty clear. Neither the 106A(a) nor the subsection (b)
exception applies in the case we're talking about, so no copyright
registration means no law suit.

Hi Tom,

Perhaps I am guilty of not having followed the thread of discussion,
but I was responding to the topic. Insofar as TV coax goes, I
presumed this was on the subscriber's side rather than the service
side. I say this because, to my problems described, I already
expected that my radio shack coax was sub-grade compared to the
service coming to me. In that regard leakage is obvious and
differentiable - of this there can be no doubt. I do not think it is
a problem of leakage into the service cable, but rather the
subscriber's cable. My home is completely wired with cable (I did it
myself, and have only myself to blame), and I did observe proper
termination conditions so no cable is floating.
As for the difference between -40 and -200 I can only say that this is
relative if it in fact is applicable to my discussion at all.

Sorry if my inclusion into this thread was confusing the issue.

"He told me that he had to read what he typed to know what he heard."

Then he hadn`t understood what he typed. His keystrokes were "conditioned responses" to the unique sounds of Morse characters. It`s the same as monkeys do when they are trained to push certain buttons when they see certain lamps flash on.

Morse code is a set of symbols used to represent letters and numerals. It is only a language if poetic license is taken with the word, "language". In the sense that there is the languages of love and that there is body language, these interest me, Morse is called a language, too. With such a broad definition, anything of significance is a language. Ideas can`t be exchanged with clarity if fuzzy definitions are used for their words of expression. Fuzzy definitions are fine for poetry, comedy and other entertainment, but not for serious communications.

Best regards, Richard Harrison, KB5WZI

Hi Dennis,

I shall defer to your obvious work and superior effort.

I think we can both agree that NO ONE here will suffer any consequence but nuisance. Myself, I have never taken any threat seriously, and I am simply amused at the feeble nuisance attempts that go to confirm the lack of character. However, having said that - I am simply preaching to the converted.

Do you have any insight into the Gaming Regulations for Mass.? It seems to me that there should be some interesting laws in regard to setting up and operating an unregistered Lottery. The penalties phase may be anticipated already given that the "offended author" seems to have gone to ground (hunting term, not an RF pun).

I have just moved into a condo about 40 miles from NY City. We are not allowed to put an antenna on the roof and theres no way to run a wire from the attic to where the stereo is. The indoor dipole is pretty much useless. The condo has an outside balcony with a railing and I had an idea that I might be able to build something inconspicuous to put on the underside of the railing or between the railing posts and the edge of the balcony. Interestingly, the balcony faces New York City. My thoughts were that I might build a multi element antenna, using thin copper elements and spacing them very close together. My question is, is there a minimum distance required between the elements or can they be real close together? What effect does the diameter of each element have on its ability to receive? What lengths should the elements be? How do I link the elements to each other and then to the lead? Is there a better alternative? Any other suggestions?
Look forward to learning from your expertise.
Thanks
Ray

>Steam played a central part in the emergence and growth of the
>railroads. How many steam locomotives are at work today?

A few. They were mostly replaced by diesel-electric locos for one reason: The
diesels are cheaper to run. Railroads in the USA are almost all private
companies, and cost reduction demanded they use the less expensive method.

But diesel-electric locomotives are not the most efficient, nor the cleanest,
nor the most powerful. Electric locomotives are. But the cost of electrifying
the right of way is so great, and the tax burden so oppressive, that most
American railroads are not electrified.
>
>Diesel works better for railroads today.

Cheaper. The diesel/electric system was not originally developed for railroads,
though.

>This doesn`t stop aficionados from loving steam.

Nope. Railroads that are "amateur" (that is, done for their own sake) are
almost all steam. That tells you something.

> op does not hear characters, he hears ideas.

Actually, in text based Morse he hears either characters of the alphabet
or words of a particular language. Morse code is an Input/Output function.
It is NOT a central processor function. Language exists at the central
processor function level, i.e. in the brain. How many ways are there to
input the word "tree"?

You can hear "tree" spoken. You can hear "tree" sent
in Morse code. You can read the word "tree" in text. You can read the
word "tree" in braille. You can read the word "tree" sent as letters
in American sign "language". All those are Input functions. The point
where you start dealing with the word-concept "tree" in your brain
is common to all the above methods of input. "Tree" is an English word.
If you were dealing with a different language, it wouldn't be the word
"tree" with which you are dealing. The Morse code word "tree" is a word
from the English language, it is not some separate Morse code language
word. Human beings usually think in their native language and that's
never Morse code. When you hear - .-. . . you are converting a
coded English word into an English language concept which represents
an object in reality. You could learn to do the same thing in ASCII
at a slow baud rate.

I've already said they didn't use Morse code. I am certainly not badmouthing
the mode. I am badmouthing code-tested hams using Morse code equipment
to jam ham frequencies. What is it about a string of 'dits' or a
string of 'dahs' that you do not understand?

> >I have heard it.
>
> But have you SEEN it? If not, how do you KNOW they were using "Morse

Of course, a ham is going to whip up a 555 circuit to send a pulse
train when he has an electronic keyer sitting there on the desk - or
program a computer or play a tape recording. Give us an ever-loving
break, Jim. You are just blowing smoke.

> Point us to the NALs. Otherwise you're just blowing smoke and
> badmouthing.

Look at the NALs issued to code-tested hams for jamming. I've have
personally heard them using electronic keyers to do their jamming.
I'm sure you have also and refuse to admit it.

W8JK antennas are big suckers!basically they are multiple wavelengths of
fractional wave sections connected by other sections at right angles.
imagine the size of a 160m W8JK.
4 or 5 times 160 meters long and 1/4 of 160m tall.
4x160=640m (0.64KM) 0.25x160=40m
(over 3/10mile long by 130ft tall)

In a halfwave antenna, the current is at maximum at the feedpoint and
the voltage is at maximum at the ends. Same for a 1/4 wave vertical and
its 1/4 wave radial. That's what Pete was referring to. If you're using
a magmount two meter antenna on the roof (or anywhere else) on your car,
you don't really have an accurate 1/4 wave ground plane, so..... all
bets are off on the ground plane part. It makes a good ground plane for
returning antenna currents but since it's no longer a resonant 1/4 wave
the voltage won't be the same as if it was. I've never experienced a
"hot" car body from being used as a ground plane, and I've been around a
LOT of them (mostly non-amateur installations).

What all you code bashers refuse to recognize is that written or spoken
words have meanings. So do the sounds of Morse code when learned to
fluency.

Your definition of the word'language' has support in most any
dictionary.
So does mine.

Dick Carroll wrote:
"---written or spoken words have meanings. So do the sounds of Morse code when learned to fluency."

A wheel is a car part, not a car.

An alphabet is a set of letters. Letters usually represent word parts, not words. A word has uncertainties of meaning without some context. The context comes from a sentence constructed by the rules of the language.

All Morse code does is substitute an unusual set of symbols for those normally used to transmit and record a language. English is a language. Morse code character "di-dah" and alphabet character "a" are symbols for an element of the alphabet used with the language.

An alphabet is not a language and neither are the symbols which express the alphabet used with the language for transmission or recording.

Yes. I would recommend you get a copy of the July 1970 issue of QST. That article also refers to an article in January 1938 QST. Both articles are written by John Kraus. His book "Antennas" mentions the W8JK array also, and you really ought to have that book in your library if you want to learn a lot about antennas anyway.

Measure how much space you have on your balcony, and then go to Radio
Shack and see what they have in stock :-)

FM beams like these aren't very expensive, and building them would
probably be a real hassle, unless you just like to fiddle...

Would an outdoor dipole be useless too?

Put your dipole or FM portable radio in possible antenna installation positions to test for signal strengths.

When you`ve found a usable signal, you will be able to determine your antenna needs.

Window frames and other pieces of structure can sometimes be used as "slot antennas". You may get out the clip-leads and experiment.

How are you receiving TV? Can you use the same antenna or cable for FM too?

Best regards, Richard Harrison, KB5WZI

1026. Anyone use an M2 6meter HO Loop for base?

(May be repeat - first ones didn't show after 24 hrs.)

Have three 40', two 60' and one 80' crankups for sale. Light duty,
custom made for wireless cable. Used for site survey. Galvanized. 40'

are 2 section, 60' has 3 and 80' has 4 sections. (about 2-1/2' overlap
per section) Have driven rod type base for most. Will throw in guy
wire and set of 4' earth anchor screws. All neck down to 6" face on
top section. Top section has brackets at top for mounting 1-12" mast.
Would be good for verticals or small/medium VHF/UHF beams.

Asking $125 for the 40' ones, $175 for the 60's and $250 for the 80'

LOCAL PICKUP (I've moved them all once!) Central Mississippi area.

Email direct for details. I am in and out so don't fret if reply takes
a
day or two. - Thnaks. Bruce, KD5IUG

Building a three element three-band trapped Yagi is a major undertaking I would not attempt and I've built some large, complex beams. Plus, as you point out, the materials specified in a construction article written in one country probably won't be available in another country except perhaps in western Europe. I don't know of any "how-to-build" articles on 3el/3 band Yagis, my ARRL Antenna Book doesn't have any. Even if there was such an article here the elements and other components would be specified in inch sizes which are not available in countries which use metric sizes and that can make a big difference.
>
If I were in your circumstances I would seriously consider a 2 element 3 band Cubical Quad antenna instead of a Yagi. 2 element quad performance is very much in the same league as small trapped Yagis. The big advanatges of a quad in your situation are that the construction is simpler, constuction accuracy requirements are much less demanding, tuning is much easier, materials are more or less common everywhere and inch/metric conversions are simple and don't affect the design parameters.
>
Quads are awkward things to handle and install. But they have smaller "footprints", are light and do not require heavy-duty rotators and it's been said that they perform better than Yagis when installed at lower heights vs. a Yagi.
>
The following will lead you to a lot of quad design & construction resources. Note the availability of several books on the subject.

So when one is copying 5 letter groups, that can be decrypted at a latter time, in a language the operator may not even know where is the language? What is the language?

You noted "body language", if one accepts the definition that the conveyance of meaning or communication is a language then the need for weeks of picking fly deification out of the pepper becomes moot.

Most of the people on here appear to accept that definition, with the exception of a few curmudgeons that enjoy tweaking others for their own amusement.

Simply build two identical dipoles. Use one to transmit the reference signal and one to receive. Adjust your transmit power, and at various output levels plot the FS values. This antenna becomes your dBdr or reference dipole. You may then compare the antenna under test with the previous calibrations.

I agree with Stan. Another idea to look at is the Moxon Rectangle for 3 bands which has no traps and is relatively low tech. Recent articles in QST [June 2000, pp38-42] and RadCom [October 2000 pp61-62].

So let's see..... Unless you knew the Italian language (I don't) If I were to walk up to you and say Io non parlo Anglais. You would have no idea as to what I said. You might even ask "What language is that?" And if I walked up to you and said Dah Dah Dit Dit Ah Dah Dah Dah Dah Dah Dit Dah Dit Dah Dit Dah Dit Dit Dit Dit Dit Dah Dit Dit Dit Dah Dit Dit Dah Dah Dit Dit You would again have no idea what I said. If you knew the italian language you would have known that I do not speak english. And if you knew morse you would know that I said "Good Afternoon Old Man. How Are You?" To me language is just an abstract. It means things to you because that's what you were taught. It's just a means for people who were taught the same thing to communicate. If you speak to someone in French and they don't know french they won't understand you. If you speak to someone in morse and they don't know morse they won't understand you either. it won't matter that you both know english or cobalt or unix. you chose the wrong language to communicate with. Language is a communications tool and so is morse. Having said that and stating that I work better than 98% CW (because I truly love the sound of it and because I am impressed with myself for taking the time to learn and understand it) I will say that I don't believe there should be a code requirement any longer. I do believe that Technical testing should be kept up even improved because that's where the future of this hobby should be going. There should also always be a part of the hobby for those of us (Dare I call myself an old timer) who enjoy using CW. Who have worked for our right to operate and who don't want to mix it up with the sidebanders or the packeteers. There. I've said my piece. Now I can go back to just following this endless thread.

I agree with Brian Kelly's posting. I also would not attempt
a tri-band yagi. Some time ago I thought I might like to build
one, just like you. I searched everywhere for construction
articles and was suprised to not find any. I checked many issues
of the ARRL Handbood, various Antenna books, back issues of
QST, and all over the internet. There were lots of single
band and some dual band, but not tri-band.

It seems that when you start making the elements do double
and triple duty, by using traps, the spacing becomes very
critical and matching can be very hard to deal with. I finally
just bought a used tri-band yagi at a ham fest.

Brian's suggestion to try a quad is also good. When I
couldn't find tri-band yagi construction articles, I started
to look for quad articles. There are lots of construction
articles for 2, 3, and 5 band quads. Great antennas and
construction materials shouldn't be to hard to find or
substitute. It's just a bunch of wire and sticks.

Good Luck

M1nn0w wrote:
"To me language is just an abstract---."

I might be put off by a a merger in Morse for the character "U" and the "question mark". But, that`s nit-picking.

I used to write programs in COBOL, which is, if I recall, an acronym for "COmmon Business Oriented Language". As Ann Richards used to say, "You can put lipstick on a sow and call her Monique, but she is still a pig." Cobalt might be more fun, if it didn`t leave you cobalt blue.

That Unix is called a language, even the ones and zeros are called "machine language", comes from ersatz (substitution) and similie (a resemblance). Like Ann Richards` pig, it doesnt make them the real thing.

>Ray

Well, I don't live in an apartment, or NY for that matter, but
I still use an indoor antenna for my FM reception.

Since you have a balcony, it usually means that you have some
kind of arcadia door for access and possibly a curtain that
covers the arcadia door, from the inside. My arcadia door
is about 10 feet wide and I use the curtain rod as an antenna.

It does a great job. I just run some coax from the receiver
to the curtain rod and connect the center conductor to the
curtain rod. I did, however, make sure that all of the sliding
connections, on the rod, were secured with screws, so as to
make a good connection.

You loose nothing by trying it and gain everything if it works.

Hi Richard,

Well, my first question, at least, was an honest attempt to get at the root of the problem you saw. Do you know for sure that it's the fault of single-shielded coax, and not, for example, a poorly-shielded TV front end, or a common-mode to differential-mode conversion problem? I know the problem of which you write, having seen it myself, but I would not jump to the conclusion that it was the fault of the coax, necessarily. Based on what others here have posted in the past, and also on some measurements I've made myself, I'd be very careful to check out what other ways the signal might be getting in.

In any event, for a home TV antenna distribution system, as opposed to a system that distributes a cable signal (offset in time and possibly carrier frequency from the broadcast signal), shielding, however you define it, probably isn't as important. Signal transmission integrity (reasonably flat frequency response, reasonably low attenuation, reasonably low reflections) is, I believe, the key issue. I would normally expect that there just won't be significant "bad" signals trying to get in, and leakage from the coax to the outside world similarly won't be an issue. If the coax runs by a strong noise source, one should look carefully at common-mode issues...and probably try to avoid running too close to such a noise source in any event.

Cheers,
Tom

Mine came with instructions. Bought it last spring and assembled it in
basement exactly as instructions said. Worked good on FD with my MFJ-986
tuner on 80 meters, but poor on other bands. I did not short feed line and
work on 160. Don't know why unless I was cranking the inductor too fast
trying to find the other match points. Van Gordon said to test the traps.
They appeared good. I need to put it up and hook my MFJ-259 analyzer to it
and see if I can tune it. I have not put it up since--use a full size 160
with ladder line inverted V with apex at 95 feet and W9INN balun box at
home. Works great. I will make a note of your request and look for the
instructions. email me your fax number direct and I will fax the info I
have to you.

From: RanHefner <ranhefner@my-deja.com>
Message-ID: <93l37t$m6t$1@nnrp1.deja.com>
Source record: 172416

This may SOUND complicated, but I think it is better than trying to mount a rotor and antenna in a tree together:

1) Tie a string to the very center of the antenna and one at the front of the antenna.

2) Hoist the antenna with coax up the tree over one of its limbs.

3) Drive a 5' antenna mast into the ground about half way directly under the center of the antenna.

4) Mount your rotor on the mast.

5) Use 1" PVC tubing to make an "L" shaped extension. The short end will mount into the rotor and the long end will point NORTH when you set-up your rotor.

6) Tie the string from the front of your antenna to the front of the PVC extension.

When you turn your rotor, it will turn the antenna and you don't have to damage the tree by "hard" mounting the antenna.

Source record: 172417

Ray wrote:
"We are not allowed to put an antenna on the roof---."

A slot 59 inches long will be resoonant about 100 MHz. Twinlead can be attached to take away the signal at the middle of the slot, one wire to each side of the slot in a conducting sheet, with a slot an inch or so wide.

A vertical slot is horizontally polarized, but today most FM stations transmit with about equal strengths at vertical and horizontal polarizations. So it makes little difference if horizontal or vertical polarization is used for the receiving antenna.

The slot can also be made in a metal cylinder (pipe) if a conducting sheet is not handy. Length and diameter of the pipe are not critical, but bigger is somewhat better.

The slot has the same gain as a 1/2-wave dipole.

Best regards, Richard Harrison, KB5WZI

1046. Re: Calibrated Dipole for FS measurements?

Newsgroup: rec.radio.amateur.antenna

Source record: 172418

For what frequency ? If for anything around 6 meters or much lower the height above ground will be difficult to compensate for. The arrl handbook used to have a dipole for about 432 that had a very repeatable gain. It was really a dipole over a screen reflector or something like that and had around 5.5 db gain in refferance to a dipole.

of 'dits'
> or 'dahs'.

You wrote "Morse code KEYS" (emphasis added) were used. Yet you provide
no references to NALs to back up your claim.
>
> > Could be. How do you even know a keyer was used unless you are at
the jamming
> > site?
>
> Are you incapable of recognizing an electronic keyer?

Not at all. I've seen many of them. Used a few, too. I prefer a
Vibroplex bug for sending Morse.

I can't tell from listening when a station sending Morse is using an
electronic keyer unless the station says so or there is some other
method of knowing. And neither can you, Cecil.
>
> > "Don't GENERALLY do so?" Nonsense. They are so rare that NO NALs
have been
> > issued by the FCC for such use of Morse. None. Not any at all.
>
> That's like saying no one has ever dunked a basketball while wearing
> a straight jacket.

No, it isn't. Not at all.

For one thing, dunking a basketball while wearing a strait jacket is quite difficult if the jacket is worn as it was designed to be worn. Almost impossible, I'd say.

Obscenity and profanity in Morse are quite easy if one is so inclined. And the FCC has been issuing NALs all over the place - but NOT for such use of Morse. Just not a problem.

> Morse code is not required for jamming.

Yup. PACTOR 2 is more effective, I would imagine.

> But Morse
> code equipment is often used by code-tested hams.

For sending Morse, yes. For jamming and other violations? That has not been proven at all. You're blowing smoke, Cecil.

Nice try substituting "equipment" for "keys". Doesn't work, though.
>
> > And what mode are they interfering with? Who are they jamming?
>
> They are usually jamming nets, e.g. the Liberty Net.

How do you know the ja,,ers are even hams?
>
> > Where are the NALs?
>
> There are no jamming NALs?????

None for the use of Morse in jamming that I know of. Put up or shut up, Cecil. Stop badmouthing and wordweaseling and put up some real information. If you can.

If you are talking about doing stuff for FCC TA&C, then I'd strongly advise you get a copy of Willmar Robert's Book "A Guide To FCC Equipment Authorizations". He goes into "antenna factor", but antenna factor is a pretty trivial calculation with a dipole. More important is how you feed it (balun) and Roberts goes into a long song and dance about that sort of stuff.

It appears to be typed (on a real honest to God typewriter!!) and self published. Last known phone number was 904.427.3612 and the location of the publisher was New Smyrna Beach FL.

If you *really* want the antenna factor for a standard dipole, it is

K = 20*log f (in MHz.) - G (in dB) - 29.78 dB and since G for a standard dipole is 2.15 dB, the whole mess reduces to

K = 20*log f - 31.93 (plus balun loss, plus cable loss).

A non-ham friend of mine has a 36 foot sailboat and is looking into SSB gear for it. He's decided to get his ham license as well, so he can operate the HF bands while at sea. Given the requirement to be able to hit the marine frequencies (I'm totally ignorant of what frequencies they are) as well as, say, 20 meters, I wonder what experienced sailor/hams are using for an antenna?

Hi Tom,

My response was not a criticism, I dropped into the thread late and thought I might be introducing some branch to the discussion.

As for this being a problem of the TV (for one reason or another) I would say that I narrowed this down through a process of elimination rather than through verification. I have no reason otherwise, but fully expect this is a cable problem.

The local signals are strong as is evident with an 18" coax draped nearby (and moved to optimize the signal) that is sufficient to watch those three channels without snow or noise. That is, the coax connected to the jack in the back had sufficient unbalanced currents to find their way into the unterminated end. Interpretations of this one clue may vary. Another clue is that there are far more over the

air signals than these three (of admittedly different signal levels), and yet they do not present the same symptoms (again, they may be too weak, but beat patterns are quite easily viewable for large S/N ratios). In fact, these other over the air signals don't even register without a real antenna.

Most of my friends say the pictures from other channels are digital clear (in fact it is still the old, but upgraded analog system... the new distribution amplifier sits 20 feet from my house). This suggests that other paths in may be possible, but the principle path in still exhibits separable characteristics (the three beating and overloading signals are those I can also receive without an antenna and the feed coax is completely disconnected). In other words, the service appears to be excellent to the characteristics you describe as desirable above.

I have an especially long run of coax from the service connector (some 50 - 60 feet). The only remaining possibility is connectors not tightened enough (a common point of leakage too).

As for external noise generators along the path - there is no issue in that regard. The house, aside from the transmitters, is relatively noise free from HF to VHF at least. I can induce noise, by turning on light dimmers, but this wholly outside of the discussion now as I can prove that noise is a function of conduction, not radiation (and the coax path is not in a conduction path).

During my time at the bench, I used triax to eliminate interference from precision calibrations (SWR measurement is impossible otherwise) in the GHz regions; and it was definitely needed because sources and detectors are never completely screened. I think you and perhaps Tom make the same point - but in the GHz regions I was much more susceptible due to proximity. Recall now, that interference leaked into a receive path is much more noticeable than strong transmit leakages out are to remote and rather more passive equipment. That is, of course, with the acknowledged fact that (as in real estate) location is all.

This may answer your question, it may even confirm your suspicions in spite of the spin I impart to the same symptoms. Such is life.

1061. Need design for endfed 80/160M wire antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-12 02:52:38 UTC
From: Paul Lusardi <n0vlr@fyi.net>
Message-ID: <3A5E7175.CA96C53F@fyi.net>
Source record: 172289

Hi, I am looking for a design for an end fed wire antenna -- I am
nhoping to not use an expensicve tuner in the process.

my layout is as such:

```
-----------------------------------------------------------------------
X (shack) 370'
---------------------->>

100'
to
here
**-----------------------------------------------------------------------
```

there are some 30-40' trees along the top line(back of property) and
some 30' trees along the 100' line(front of property). the reason I am
asking about an end fed wire is because I beleive that you *should not*
bend a wire antenna at 90 degrees

restriction: I can only run wires along back of property or from the
shack to the ** marker

any ideas? home brew or product ideas are welcome

thanks

Paul N0VLR

Kevin,

The deviation of the FT-50 is wider than FRS uses, so it would have a tendency to be hard to understand. Also, unless you use 12.5 step rate, the FT-50 will not tune to the FRS channels. Even when the proper frequency is displayed, I would check with a counter to be sure. Last, but not least, it is not type accepted for FRS use.

FWIW,

David

I've never personally used one but I think some of the east coast guys do. But it seems that there is some kind of severe mismatch that causes audio distortion such that all of their "R's" seem to be missing.

Apparently this is more of a problem on h-f, particularly the longer paths to the west coast where their signals are almost unintelligible. However, I understand they work quite well for local QSOs on 2m FM in the Boston area.

> to another band.

If they're so compatible, why have separate sub-bands? If CW is so great, let it stand or fall on it's own merits, don't try to protect it with a separate allocation.

Somehow this thing has drifted so far off base it's embarrassing to contribute to it, but NO ONE I've heard of is proposing banning CW, if you like it, fine. If you can find someone else who needs CW proficiency to feel better than the next guy, go ahead and talk with your fingers to him/her.

Stop acting like CW is next to Godliness and all the rest of us are sinners and you'll have more friends.

> Happens all the time now, but won't when CW is banned. And make no

Jim, N2EY wrote:
"None for the use of Morse in jamming that I know of. (NALs)"

Most of all, a jammer wants results. CW is not the best way to get results. If it were superior, government and political propaganda agencies would use CW in their battles to drive away listeners. They don`t often use CW for that.

I worked for years in shortwave broadcasting. Our listening posts around the target areas logged all the jammers on our programs. More than 50 jammers would appear on one frequency. Some were high-power sky-wave jammers and some would be local jammers in city neighborhoods.

How did we know about the numbers? Most jammers identify! Beyond that, we triangulated and tracked them down. We could not exterminate them, but we knew who and where they were. Policy might have changed to allow eradication, but I expect that like roaches such action would have just prompted more to appear. The jammers were our well known neighbors on all of our frequencies. We had to publish our schedules in advance for our listeners, even when some were those in charge of jamming. In spite of jamming we punched our programs through, and we never went unheard or unheeded. We were charged with causing economic collapses, military uprisings, and revolutions. We were innocent of some of the charges!

A multitude of modulations were tried by the jammers. The variety seemed to be winnowed and a few of those modulations probably thought to be effective against us seemed to be dealt out to most of the jammers after awhile. News of the jamming efforts often circulated through our organization. We all wanted to know how we were doing. I never heard of CW being used. Big investments were made to obliterate us, but we always managed to get through, but with some gaps in coverage. If CW were ever in the competition as a jamming signal, it was eliminated, and probably early in the game.

So, would an experienced operator use CW to jam or make profane remarks? Probably not. A modulated carrier makes more intentional mischief and draws a wider audience to shock with profanity.

The weak-as-water point coders seem trying to promote is that people trained in Morse are of better character and don`t violate the rules. They claim there are no violation notices for deliberate use of CW to jam or pollute the air with profanity. This is supposed to prove that CW makes operators righteous.

The proof of the coders claim would be more convincing if it it sorted violators by whether they had been code certified and their percentages

of the total in their particular group.

Whatever group a jammer comes from, if he is a real troublemaker he is likely to go beyond extemporaneous acts. He will likely treat his audience to prerecorded programming, musical passages, sound effects, insults. barbs to specific individuals,etc., and all in plain but disguised language to reach the largest possible audience. Could this be so? Yes. It`s all happened repeatedly and involved several individuals in this community. Some were ordered to pay large fines and lost their licenses. These cats may have known CW, but it would not have served their purposes at all.

Would elimination of legal voice operation on the bands have any effect on egregious violations involving weird modulation. I think not so long as the ham`s receiver was capable of demodulating a signal.

Best regards, Richard Harrison, KB5WZI

Yes, that is an eminently noteworthy feature of this 'discussion'. The
Code Opposers, to a man, insist on honoring only their own choice of
definitions of the word 'Language', while every dictionary I have
consulted has numerous differing definitions, a number of which clearly
qualify Morse code as in fact being a language.
That pretty well sums it up.

That does not mean that Morse is not a language.

If a child's parent always communicated with him in a series of clicks and pops based on Morse code, the child would indeed communicate in a Morse language clicking and popping back at the parents without a clue as to how normal spoken English sounds.

So there we have it. You win the argument because you delete from consideration the very things that *are* the Morse language by saying that they are not strictly the telegraphic alphabet known as "Morse".

> If Morse actually were a language, then translating the
> message into Morse would make it understandable
> by anyone fluent in Morse, whether they knew English or not.

See, you made yet another terrible generalization.
There are many Morse languages.
We were talking about the Morse language that is based on English.

> But of course that isn't true, because Morse isn't a language.
The three dots on a traffic light are a language too.

Speaking for myself, I assert that when I see the red dot, I don't translate that into English, and say, "okay, 'stop', I guess I better stop".

I understand the language of traffic lights directly without having to know the English meaning behind the red dot, amber dot, and green dot, and flashing variations thereof.

When my first two sons were very young, I didn't tell them what the lights meant.
For month or two when we were in the car on the streets, I pointed out the lights but did not explain them as traffic control devices.
Nonetheless, eventually they understood what the lights meant from how I and other drivers reacted to them (although the other drivers often confused the issue).

They didn't have to know the English meanings at all.

By the way, although computer languages are truly languages in their own right, most are based on English.

1071. Antennas for apartment dwellers?

Newsgroup: rec.radio.amateur.antenna

I would like to either erect a dipole antenna or vertical in my backyard, here is my problem. I would have to space the dipole off of the wall of the apartment somehow because there are no supports anywhere in the yard to use, and I would be limited to one band, probably 40m. Will the performance be degraded by any material contained in the brick? As for the vertical, I may use a mobile whip or maybe a screwdriver. What would be the best ground system for this type of antenna? I am using a TS450 with built in tuner. I can't mount it too high or out in the open. I was lucky to get away with the satellite dish!

Thanks for the help

Max VE3TMT

1072. Help with KLM Triband antenna

Source record: 172295

I have obtained a used and abused (when it was taken down by the owner several years ago, the elements were separated from the boom and the boom and elements were left in the bushes at the edge of the property). The owner (a friend) is selling the house and he offered me the antenna. I retrieved it and dug it out (It was buried by accumulated pine straw - which may have protected it). It seems to be in pretty good shape - considering. Some of the pieces of the elements are bent, but look like they may be straightenable. I haven't gone through the elements in detail yet, but so far, apart from some rusted hardware, it looks like the only broken piece is one of the element to boom clamps.

I am looking for a copy of the manual for this antenna. I'd rather not take the elements apart (they look a lot more complex than my Force 12 C4S) until I'm sure I know how they go back together. The antenna is a 20-15-10m tribander. It has 6 elements. I believe it is either a KT34A or KT34XA. Can someone tell me how to tell the difference.

I'd also welcome any suggestions on rebuilding. My planned approache is to take everything apart, clean and straighten (or replace) the individual pieces then put it together as if I were building a new one, but currently all the elements are as they were when it was taken down, other than we separated them in the middle for transport, but we then taped the two halves together so we know which goes with which.

As it looked pretty straightforward, I began my cleanup on the boom (a lot less parts). It cleaned up really well, which gives me hope for the elements.

Thanks,
Mark, N8ME

>well together.

Here's what I've used for coax-fed dipoles fpr the past 17 years or so. Only works with small diameter coax, though:

Start with a piece of "2 inch" PVC pipe about 5 inches or so long. Drill 1/8" holes about 1/2" in from each end for the antenna wires. Drill pairs of 1/4" holes on the "sides", right in the middle. Two more holes about two inches apart on the top are for a halyard to support the antenna if it's put up as an inverted V. Looks like this (side view):

```
______ _________ _______
I U U I
I I
I o O O o I
I I
I_______________________I
```

o = 1/8" hole for antenna wires
O = 1/4" hole for tywraps
U = 3/8" hole for halyard

Other side drilled the same.

The coax is wrapped around the middle of the insulator and secured with black UV resistant nylon ty wraps. The end of the coax is tywrapped to itself and points down, so water stays out. The whole thing is weatherproofed with rtv or spray lacquer after connections are made. No metal in the insulator at all.

I can supply bitmap drawings if needed to make it clear.

: say, 20 meters, I wonder what experienced sailor/hams are using for an
: antenna?

For the HF frequencies, the backstay is the most common antenna. Of course, it requires an antenna tuner.

The usual method is to place an insulator a couple of feet from the mast head. The antenna tuner is coupled to the hardware that fastens the base of the backstay to the boat (the tuner is placed inside the hull). Most boats of that size have a lazarette or deck locker that provides access to the inside of the hull at the right place.

It is wise to put an insulating tube over the bottom 8-10 feet of the antenna - to keep people from getting accidental rf burns if they touch the backstay during transmissions.

Floyd:

Backstays as antennas...

Safety of life at sea demands that one ensure sure that backstay antenna setups are first and foremost structurally sound and do not compromise the mechanical integrity of the backstays. Then, and only then, should one consider optimizing the electrical and electromagnetic efficiency of an antenna which is an "auxilliary" use of such basic structures.

Lots has been written in the blue water sailing literature and periodical press about HF antennas on sailboats, some basic research by your friend is in order.

If the safety of life at sea is at stake, and one is going to [perhaps] compromise their marine safety by modifiying basic boat/ship structures like stays and or masts to accomodate an HF antenna installation, they should consult not only HF antenna experts, [i.e. like gurus in this news group], but also competent marine/naval architects/engineers who are qualified to design and "sign off" on the structural integrity of masts and backstays, etc...

Just a word of caution...

-Peter K1PO

There isn't any way that I know of to feed an endfed wire on two harmonically-related bands without a tuner. See Dick Carroll's post for a simple tuner.
>

> there are some 30-40' trees along the top line(back of property) and

> asking about an end fed wire is because I beleive that you *should not*
> bend a wire antenna at 90 degrees

>
It's OK to bend the wire.90 degrees. All it does is provide a different pattern from a straight wire which you can't control anyway. Just don't fold a wire back on itself.
>

> restriction: I can only run wires along back of property or from the
> shack to the ** marker
>
> any ideas? home brew or product ideas are welcome

>
Endfed wires are quite simple and effective, I've used several over the years. For 160/80 I'd make the wire 250-260 feet long from the tuner to the far end. Run it any way you can as high as you can. I use a bow & arrow to install wires thru trees. #14 stranded THHN insulated "house wire" from Home Depot which costs under $20 for 500 feet works fine. #12 would be a better idea. Leave a good bit of slack in the wire between trees. I use a simple egg insulator at the end and a nylon cord tied to the last tree to keep the wire from snaking back out of the trees toward the shack.
>
But that's only half of the antenna, the other half is the ground system. Ideally, you should install a ground rod as close as possible to the tuner and ground both the radio and the tuner. I also always install a counterpoise which is made from the same wire as the antenna.100-150 feet will do, there's nothing critical about it. I run my counterpoises along fencelines, anywhere where they aren't a tripping hazard or subject to lawn mower damage or "wifely dissent", etc. If I have to run it over open lawn I bury it an inch ot two below the surface.
>

A 250 foot wire on 160 & 80 will be voltage fed on both bands which means
the feedpoint at the tuner will be "RF hot". Not a bad thing but it can
result in "RF bites" if the ground rod isn't close to the tuner. So I
always install a choke balun in the coax line between the tuner and the
radio.
>
One caution: Long wires in trees are lightning magnets. I *always*
completely disconnect the antenna from the tuner and via an alligator clip
and attach the antenna directly to the ground when I'm not on the air.

Depends on which definition of "language" is used. Since we cannot agree on
which one to use, I'll avoid the use of the word "language" and come at this a
different way.

You wrote:

"but they are just "written English" or "spoken English", for example. They are
not languages by themselves."

The important thing is this: Written English and spoken English are not
identical. There can be a BIG difference between hearing words spoken and
reading those exact same words written down. Two different methods of
expression - both of them "English", but definitely not the same.
>
>The same is true for Morse code,

Not so! When used the way most hams use it, "Morse English" is a method of
expression that is different from both "written English" and "spoken English".
It's aural (not "oral") and has unique characteristics.

> ASCII (or any of the other methods of
>encoding characters). They are simply that - codes.

Not as used by hams. ASCII and other codes are used differently - the human
doesn't interact with them directly. They are simply used to convey the written
English from one place to another. "Manual" Morse is very different.
>
>: Your definition of the word'language' has support in most any
>: dictionary.
>: So does mine.
>
Thus the debate is diverted from the important facts. Morse is a different
method of expression, with several very real advantages and one or two
disadvantages - that's the important thing.

>
>If they're so compatible, why have separate sub-bands?

Because they are NOT so compatible. There is very little use of Morse in the HF
'phone bands. The author was talking about using it as a backup when SSB fails.

> If CW is so great,
>let it stand or fall on it's own merits,

It does! There is no requirement to use the mode at all. Just pass one test one
time.

>don't try to protect it with a separate allocation.

There is no separate allocation on amateur HF/MF!!

The only "CW only" subbands in the US are 144.0 - 144.1 and 50.0 - 50.1. They
were created decades ago as a haven for weak-signal work like EME.

ALL of the so-called "CW bands" (that is, the segments where 'phone is not
permitted) authorize Morse AND RTTY/digital modes (that do not exceed a certain
bandwidth). PSK31, for example, can go anywhere in those segments. But
RTTY/digital modes are NOT allowed in the "'phone bands"! It's analog voice
modes that are "protected" by having their own separate allocation.
>
>Somehow this thing has drifted so far off base it's embarrassing to
>contribute to it, but NO ONE I've heard of is proposing banning CW, if you
>like it, fine.

I have read some discussions that urge BANNING CW. Not just the test - the mode
itself. Sure, they're a tiny minority, but they DO exist.

>If you can find someone else who needs CW proficiency to feel
>better than the next guy, go ahead and talk with your fingers to him/her.

That's not why hams get the proficiency.
>

Don't assume he'll need two radios - he can operate a maritime type-accepted radio on 20 meters. I have a regular sched with a ham out in the pacific on a sailboat, and he works the HF ham bands and maritime bands with one rig.

My friend's biggest antenna propagation problem was getting enough metal screening down in the bow of the sailboat to act as a "ground".

Date: 2001-01-12 14:00:29 UTC
From: Larry Gauthier <larryg_AT_ismi.net>
Message-ID: <3a5f0ecb$1@news.ismi.net>
Source record: 172308

I just put up a new tower, and in addition to the quad up there I would like to build a homebrew 30 meter rotary dipole. However, I need a boom-to-mast clamp that will attach to the 2" mast - and thought that someone on this news group probably has a collection of used clamps from previous antenna projects. Doesn't have to be heavy-duty - this will be a coil-shortened dipole for 30.

Anybody? Please send details to my e-mail address. Thanks in advance,

I thought about that after I posted and it occurred to me that a marine ssb
radio can be used legally on the ham bands, but not the other way 'round.
They're out there, too. 150 watts out, continuously tunable from 1.600 thru
29.999 Mhz., etc. Not cheap though.

Mandatory testing for an optional mode is illogical.

Mandatory Morse tests repel far more amateur radio license applicants than they attract. A large group of licensees is more likely to get what it wants from the government than a small group.

The dirty little secret is that pro-code amateurs fight for a code test to ensure amateurs are mostly pro-coders.

Some commercial users have valid claims to places in the radio spectrum. They have paid the people to use those places. The places occupied by amateurs are still owned by the people, in the sense that public lands are owned by the people.

People-owned properties should be as accessible as possible to the people who own them so that there is the most benefit to the most owners. Code testing works against this.

Just wanted to say that I did exactly what Dick shows on the URL below about
15 years ago
with a 130 foot wire end fed on 80 and 40 meters. It was between 55 foot
towers and the tuner
was at the top of one of the towers. It used a rotary solenoid and wafer
switch to select coil
taps to cover the whole 80 meter band. It was a little bit of work to build
the tuner, but it
was straightforward and worked well (or at least as well as a low dipole
ever worked on 80!).

From the Kennedy-Nixon debate, we know that viewers drew different conclusions from listeners who weren`t watching. A similar thing happens at times between listeners and the readers of a transcript,

On-site viewers who see and listen tend to get the most information. The TV audience seems to be the next best informed. Radio listeners get less information than the TV audience. Readers are deprived of the speech nuances, as are CW users.

If we want to communicate in place of a commute, shouldn`t we all use 2-way TV to get fastest access to the most information? Bell always thought so, but never could sell it. Maybe the technology was still lacking.

CW seems best suited to a last resort.

> That pretty well sums it up.

Just what does Morse being a language have to do with the Code Tests?
Not the USE of code, but the TESTING of code proficiency?

I am opposed to the code tests. But I am not opposed to the continued
use of CW by those who enjoy it on bandwidth set aside for that
purpose. So, if opposing the tests fits your definition of 'Code
Opposer', then I am prima facie proof of your incorrect assertion that
the Code Opposers, to a man, use narrow definitions of 'language' -- as
I do not disagree with Morse being a 'language' in many of the ways
American Sign is a 'language'. To be technical and nitpicking.

Eliminating the test does not equal eliminating the mode.

I am not an amateur radio license holder but I am new to radio which makes me an amateur (Just kidding). I have gotten interested in MW radio. My question is 1) I have a R/S DX-390 (Sangean 818) and a good Panasonic table top (transistor/6 diode)that I listen too. I am looking for a good inexpensive way to improve the signal. The 390 has an external plug but the Panasonic only has two post for an external FM antenna. Is there a way to hook up a MW antenna I can use on both of these.

Any help will be appreciated.. I am studying now for my license.

Because coax is easy and convenient to install and maintain. You can bury it, you can run it near metal objects, you can do almost anything you want to with it. On the other hand, ladderline is lower-cost)$19.95/100 ft from HRO), lower loss, and it rolls up smaller for portable work. I use ladderline myself mainly because I can build an entire high-performance 2M base antenna and 80 ft of feedline (some of hte 100-ft roll is used in making hte antenna itself) for much less than even a small roll of cheap coax.

Check out http://www.tfn.net/~gfloyd7/antenna for a vertical collinear J-pole that is fed with ladderline as well as an inexpensive way to match 50-ohm coax to 450-ohm ladderline (1/2-wave 4:1 coax balun and a 1/4-wave 300-ohm matching section).

Agreed. A plain carrier is easily removed by a notch filter. A keyed carrier is
a little tougher, but can be dealt with.

So what you are saying is that CW isn't attractive for jamming purposes. That's
a good thing
>

I didn't know they did local jamming!

There's an ongoing jamming episode happening on 40 meters between Iran and
Iraq. They are both operating outside the SWBC bands. See

http://www.arrl.org

for more details.

>How did we know about the numbers? Most jammers identify!

Har! I would think you did some sort of RDF and transmitter signature analysis
too. But maybe better not to give away how it's done.

>draws a wider audience to shock with profanity.
>
>The weak-as-water point coders seem trying to promote is that people
>trained in Morse are of better character and don`t violate the rules.

Nope. That's not my point.

My point is simply that the type of violations on the ham bands being gone
after by the FCC are happening to 'phone stations, not Morse stations.
Intentional jamming, profanity and obscenity by hams actually using Morse on
the air is so rare that it's beneath the FCC's radar.

>They claim there are no violation notices for deliberate use of CW to
>jam or pollute the air with profanity.

It's not a claim. It's the truth, for at least the past 10 years.

Point me to some Morse NALs, if I'm mistaken. Lots of "enforcement log"
websites.

>This is supposed to prove that CW
>makes operators righteous.

Nope. It simply proves that hams using Morse behave themselves so well on the
air that NO NALs have been issued for such jamming/obscenity/profanity
violations for at least 10 years. Maybe longer. Such is NOT the case with hams
running 'phone. It has been reported that Riley Hollingsworth himself was
"jammed
off 20 meters" recently. Frequency was 14.275 - I don't think he was running
Morse, do you?

Maybe being skilled at Morse makes one think a little more before putting a
signal on the air. Or maybe those who choose to use Morse are the type who
behave themselves on the air regardless of mode. Maybe it's something else

entirely. But the fact of no NALs for a very long time still remains.
>
>The proof of the coders claim would be more convincing if it it sorted
>violators by whether they had been code certified and their percentages
>of the total in their particular group.

IF the claim were that Morse TESTS cause massive behavior changes, maybe. But
that's not the claim at all. It's Morse USE that seems to make the difference.

The test is a dead issue.
>
>Whatever group a jammer comes from, if he is a real troublemaker he is

>their purposes at all.

Exactly. Maybe they knew Morse really well, or maybe they learned it just well
enough to pass the tests and then forgot it. No real way to tell. License class
only tells you they got credit for passing a test once upon a time.

All licensed violators, regardless of class of license or violation, took
WRITTEN exams on the rules and regs. Broke 'em anyway.
>
>Would elimination of legal voice operation on the bands have any effect
>on egregious violations involving weird modulation. I think not so long
>as the ham`s receiver was capable of demodulating a signal.
>
Nobody's proposing that. But it might greatly reduce the incidence of
violations.

In a recent case (WA6CNQ), a two-time violator's license was modified as part
of a plea-bargain. The only amateur bands/mode he can work legally now is
HF/MF Morse. No RTTY/digital, no phone, no SSTV, no VHF/UHF. Maybe the FCC's
idea is to break that zero NAL record, or maybe the hope is he'll clean up his
act. I don't know whether I agree with that move or not - but it sure makes you
think.

>Mandatory testing for an optional mode is illogical.

No, it's perfectly logical. A license test should check for skill and knowledge
in those things that are commonly done with the privileges the license grants.

Granting privileges without tests of knowledge in appropriate areas is
illogical.
>
>Mandatory Morse tests repel far more amateur radio license applicants
>than they attract.

How do you know that? Studies and facts, please.

Note that since the massive reductions in both code and written testing of
April 15, 2000, the number of US licensees has not grown appreciably faster
than before the changes.

Suppose the Morse tests are dropped entirely, and the numbers still don't jump.
Will they be put back?

> A large group of licensees is more likely to get what
>it wants from the government than a small group.

Then why didn't the cb folks just take over in the '60s? Quality counts, not
just quantity.
>
>The dirty little secret is that pro-code amateurs fight for a code test
>to ensure amateurs are mostly pro-coders.

Not at all. There are a variety of reasons to support code testing.

And one can be "pro-code" wothout being "pro-code-TEST".

Besides, the whole test issue is a dead duck. A moot point. We're down to the
bare minimum now, held on only by the treaty. Which can't change before 2003.
>
>Some commercial users have valid claims to places in the radio spectrum.
>They have paid the people to use those places. The places occupied by
>amateurs are still owned by the people, in the sense that public lands
>are owned by the people.

By ALL the people, yes. But when used by some of the people, their very nature prevents others from using them. Amateurs "pay" for their piece of the spectrum in a variety of ways.
>
>People-owned properties should be as accessible as possible to the
>people who own them so that there is the most benefit to the most
>owners.

Sheer numbers are not the only criteria. Overcrowding leads to less benefit. How many SSB QSOs can fit in 100 kHz compared to Morse or digital QSOs in the same bandwidth?

>Code testing works against this.

So does any effective testing. Why should hams have to know the limits of the 40 meter band if its use is optional? Why should they have to know the fundamentals of SSB or repeaters if their use isn't mandatory? Go down this path, and you wind up with practically no tests at all - and chaos. Not a good thing at all.

1099. 900MHz Yagis - solid vs. tubing as elements?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-12 17:47:54 UTC
From: Tom Merendino <tmerendi@fore.com>
Message-ID: <3A5F434A.1FAD6C09@fore.com>
Source record: 172323

Hi,

I am planning to experiment by building a yagi for the 900Mhz band. Will be used for receiving only. It will be mounted in the attic, so mechanical/wind loading considerations are not important.

Is there any electrical performance advantage of using solid rods vs. small diameter hollow tubing as elements? Is there a large sensitivity to element diameter in this frequency range?

How about the boom - any electrical performance advantage of using conductive vs. nonconductive boom material? Is it better to attach the elements to a conductive boom vs. isolating them from a conductive boom (above or thru?)?

The electrical parameter I'm most interested in optimizing is the receive gain.

Thanks in advance for any experience you can share.

Nobody`s proposing that. But it might greaty reduce the incidence of
violations."

No doubt. Cut out the voice and mostly empty the bands. With empty bands there will be few violations and soon there will be few licensed amateur radio operators. Lots of space for CW die-hards, for long as amateur allocations persisted, which might be less time than some think.

Best regards, Richard Harrison, KB5WZI

But skill is tested in only ONE mode, OOK/Morse. Why is skill in OOK/Morse
as important as everything else in amateur radio combined? 5wpm skill in
Morse code is a pass/fail requirement for HF access. Everything else in
ham radio combined is a pass/fail requirement for HF access. How anyone
can consider that fair is beyond comprehension.

This has little to do with code testing. Wider bandwidth allows faster information transfer. If you have a quantity of data you can use wideband for a short time or narrowband for a long time. In the grand scheme of things, it`s a wash. Coding and transmission schemes have various efficiencies. Morse loses the efficiency contest due to a fatal flaw. A dit is shorter than a dah. End of story.

Probably the most simple antenna would be a random length of
wire, outdoors, as high as you can get it. Should work better
than the antenna in the radio. For recieving only, it shouldn't
make much difference ~how~ you get it outside...

Bill - thanks very much for your response. It would appear that you actually have some experience with the subject. The rest of the responses were typical of what one normally sees from this group - most of the "experts" assume you're an idiot, and most of the others forward on rumors they've heard.

For those obviously less informed than I, there are indeed SSB radios that are type accepted for both marine and amateur band use. The SGC-2000 is one of those. It received a very glowing review in one of the sailing magazines, in an article written by an "expert". However, in researching how this unit is performing in the fleet, we found nothing but negative comments about it's reliability and the extreme difficulty in dealing with SGC on service issues.

I've read the info in the ARRL Antenna book on sailboat antennas. A properly installed backstay vertical seemed the most reasonable to me, and I have experience with automatic tuners (SGC-230s). When my friend contacted two sailing hams he knows, they gave him quite different solutions. One guy is using an Outbacker mobile antenna (they have one model that covers the ham and marine bands - $469 or so), and the other made a 20 meter dipole using two back-to-back hamsticks. So, it appears that this odd concept that any expensive commercial antenna must be better than anything else, has followed some hams into their sailing hobby. I also wondered how many of these "land mobile" antennas have ever been thoroughly tested in a marine environment.

Thanks again.

1113. Re: Antenna for sailboat?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-12 21:50:49 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A5F7C39.5C4D7BCD@eznec.com>
Source record: 172338

This advice isn't based on sailing experience but on solid theory.

You'll find that a vertically polarized antenna will give you considerably better results for long-haul propagation than a horizontally polarized antenna. A horizontally polarized antenna will work just about the same in the salt water environment as on land, but a vertical will be much better over salt water, at low angles. If you use a vertical in a typical land-based environment, low angle signals are greatly attenuated due to reflection from the lossy ground. But the reflection is nearly perfect when it takes place from salt water. In that environment, you can actually get a pattern from a vertical that's very much like the theoretical perfect-ground vertical antenna pattern -- with the maximum value right at the horizon. Land-based stations can never achieve this unless the antenna is within a very short distance of a body of salt or brackish water. So I recommend that anyone having the luxury of a salt water "ground" take advantage of it and use some sort of vertical.

Roy Lewallen, W7EL

Thanks 'doc.... i'm using 50-ft of coax now. I would say the run is pretty much metal-free, and i would really only need about 30-35 feet of some other type of feed line. If i were to go to something like ladder line or other twin-lead feed what kind of loss would i be preventing? (50-ft 50ohm coax, versus 35-ft twinlead). Considering QRP, would there be justification to make the switch? How about with more power, say around 100 W?

QSOs
> in the same bandwidth?"
>
> This has little to do with code testing.

That's right! The issue is one of subbands for different modes.

> Wider bandwidth allows faster
> information transfer.

If and only if the wider bandwidth is used effectively. It often isn't. An SSB signal typically takes up ten times the bandwidth of a Morse signal, but it doesn't carry information ten times as fast. AM is even less efficient.

And the discussion was about access for the most people. More people have access at a given time using "conventional" methods if narrower bandwidth modes are used. This isn't just a characteristic of Morse - other modes have it too. Opening up the bands to all modes squeezes the spectrum-efficient ones like PSK31. That's not a good thing.

> If you have a quantity of data you can use
> wideband for a short time or narrowband for a long time.

Sure - if you are transferring data. If you are having a realtime conversation, it's a different game.

Most people talk in the 100-200 wpm range, but their actual communication rate is rarely more than 80-100 wpm because of pauses, repetitions and "by gollys". A decent Morse op or typist can effectively communicate in the 50-100 wpm range using abbreviations and Q signals. But the Morse and keyboard users take up far less spectrum, allowing more QSOs in the limited space.

> In the grand
> scheme of things, it`s a wash.

No, it isn't. The times people can get on the air and the bands used are usually determined by external circummstances, resulting in busy and slack times. That's why spectrum-conserving modes deserve consideration.

>Coding and transmission schemes have
> various efficiencies.

Agreed!

>Morse loses the efficiency contest due to a fatal
> flaw. A dit is shorter than a dah. End of story.

Nope. Morse doesn't need start/stop bits or synchronization. End result
is that Morse is quite good. Want some numbers? I've got 'em.

Performance will be poor if the apartment is concrete. Much better luck with cinder blocks and even better with all-wood construction.

I had reasonable luck with dipoles attached at the ceiling level, as long as possible, fed by a TV line at the corner to an antenna tune with balanced output. This worked from 10m down to 40m.

Magnetic loop is a possibility although getting one to work below 20m may be hard and tuning is very picky.

Hi Richard,

Almost ANY method of modulation suffers under such a comparison. What you say is true, quite so, but is equally true across the board and as such becomes a commonplace observation rather than a special one for CW alone. All forms of communication incorporate some form of redundancy in time, frequency or space. In fact nearly any modern digital transmission is intentionally redundant. Spread Spectrum is the class example in that regard (a simple derivative example may be found in FM mode).

What you are answering with would be called a data bit/rate/bandwidth constant, but what you are also responding to would be called data throughput. The two are not the same except by a casual appearance. In the language of computer connectivity to your ISP, you may in fact have a 56 KBaud connection that is so noisy that through all the retries you in fact only move 1 KBaud of data successfully. This is a prime example of redundancy built into a mode (in this case TCP/IP which is very like Packet).

Really, you guys talk about "language" at a truly amateur level of discussion. One of the key failures is being too close to the subject. In other words there is the underlying perception that being able to use and speak a "language" must mean that you understand the process. Wrong - you don't have to be a conductor to appreciate and "understand" the language of music - but neither does a listener of music have the qualifications to conduct it in spite of the strong feelings evoked by that act of participation. But I have already posted a response in that regard that was wholly ignored - language is not the battle you guys are fighting. You are fighting because of

language. CW is a language to a linguist, perhaps not to this crew, but that is immaterial; and the argument about being language is an element tossed in for effect only and has exhibited very little substance to support or deny the logic presented in this forum.

Hi OM,

Be prepared for the contradiction of your life. For this particular radio (I have one), a better antenna will equate to poorer performance!

The problem will be found in out-of-band (or off frequency) sources of great power that overload/desense the front end of your set. If you want improved performance, you will need an antenna tuner, or tuneable preselector.

Here in the states (and perhaps europe too), there are many local big AM band transmitters that may be so close to you (several miles) that they swamp your signal. You must reject them before they get to the antenna connector. True, you may not be tuned to them, but the front end of this set is not tuned either and will accept any signal. The conversion process will mask this problem (except in the worse of circumstances) such that it is not obvious, making this a rather tough problem to troubleshoot if you were not already aware of this design shortfall. The receiver is a good one otherwise.

1119. Re: 900MHz Yagis - solid vs. tubing as elements?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-12 22:29:12 UTC
From: tom_bruhns@agilent.com
Message-ID: <93o0fc$7pb$1@nnrp1.deja.com>
Source record: 172343

For a given element OD, there won't be any noticable difference
between tubing and solid elements.

Element diameter does make a difference. That will be especially true
for the parasitic elements, because Yagis work by having the elements
tuned to get specific phase shifts, and the tuning is affected by the
diameter. The same is true for any frequency, for a given design and
change in element diameter, expressed as a percent.

Boom conductivity does matter. A conductive boom will shift element
resonances to a higher frequency, relative to a non-conducting one. I
believe you'll see this effect most if the elements are bonded to the
boom, but to some extent even if they are insulated from the boom.

Suggest you do some modelling, or arrange things so you can easily
change element spacing and length. You may find it convenient to get a
stock of nesting brass or copper tubing from a hobby shop, and use slip
joints to allow quick changes. At 900MHz, you might even use screws
threaded into the ends of the elements to allow length adjustments. I
know it would be frustrating to me to have to build a large number of
antennas to test out variations.

Cheers,
Tom

Joe,

Being Military and moving all the time, I have run from apts to rental houses. Check with the Apt owner. I lived on the top floor of a 3 story apt for 4 years and the owners let me build a "portable" dipole on the roof. It was one of the better ant's I used on a rental. If you are high enough off the ground, you can run a long wire, weighted on the end and fed on the other end with a tuner. Just roll it up when you aren't using it.

There are also commercial units that clip on a window sill and are all band. (I have never used one) You an not beat a long wire ant when it comes to all around performance.

Hi Wes--

I've never "had" a fake or real Boston attorney (like Laura Flynn Boyle or Martha Moakley for example), but I used to date one in NH. Sadly, the prenup scared me off.

I've had lunch at Boston Chicken, though, and loved it--even though they are going out of business (a scenario familiar to many Boston Ham companies, as well).
But, enough about me. Here's the riddle:
Why did the Boston Attorney cross the road? Too drunk to say in his own lane, of course!

Opps, a bad Kennedy joke and time for pizza!

1126. Re: feedline: coax or twin-lead?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-13 00:51:17 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <93o8p2$6pb$1@uranium.btinternet.com>
Source record: 172350

Steve, your and similar questions about twin-line and coax antenna feeders occur very frequently. I'll try to summarise the facts.

(1) For the same wire gauge the attenuation (matched loss) of a transmission line is inversely proportional to its impedance Zo. Coaxial lines always have a lower Zo than balanced twin lines so for the same conductor gauge attenuation per 100 feet is greater for coax. But not very much greater when line lengths encountered by amateurs are considered.

(2) For example, the attenuation per 100 feet of 600-ohm open wire line is 50/600 = 1/12th of the attenuation of 50-ohm coax line for the same SWR. On the other hand the SWR on the 600-ohm line is likely to be higher than on the 50-ohm line.

(3) Most coax has impedances in the range 50 to 80 ohms. Balanced twin lines have impedances in the rangs 130 to 600 ohms. However, twin lines need a matching transformer or tuner of some sort at one or both ends to convert to the 50 ohms which transmitter prefers to see.

(4) But for short to medium lengths of line, from transmitter to antenna, the attenuation of both types is very small. SO PROVIDED THE SWR IS SMALL IT DOESN'T MATTER WHICH TYPE OF LINE YOU USE. Its a matter of cost and convenience of installation.

(5) Only when multi-band operation is required will a high SWR be encountered. For single-band operation it can nearly always be engineered to have a low SWR on the feedline.

(6) SWR increases the loss of BOTH types of line in the same proportion. But because the attenuation of twin or open wire line is very much less to start with the loss with open-wire or ladder line for a given length and wire gauge is always less.

(7) Again, for short or moderate line lengths at the lower frequencies, say below 8 MHz, it doesn't matter very much what type of line is used. We don't care very much if the loss on the line is 5 times (in dB) greater because of high SWR if the attenuation is only 0.2 dB when the SWR is 1-to-1.

(8) On the other hand it is very often more convenient to install a coax line all the way from antenna to transmitter than an open-wire line.

(9) It is not true to say the loss on coax is greater than on twin line. To keep matters in proportion it is important to remember the attenuation and losses on coax can be less than on open wire line if

the coaxial inner conductor has a diameter several times greater than the open wire conductor diameters even with moderate SWR.

(10) So the choice of type of line to achieve a particular level of radiating efficiency.is always a matter of convenience. and economics. How much are you prepared to pay for an increase in signal strength of 1dB or 1/6th of an S-unit ? 1dB is a change in signal level which is undetectable at the receiving end.

Download in a few seconds program VARNEY to experiment with different dipole feedline impendances and conductor diameters. You will find the choice is not at all critical. Not zipped up, one small file only. Run immediately.

>at times between listeners and the readers of a transcript,

I agree 100%. Listeners thought Nixon won. Viewers thought Kennedy won.
>
>On-site viewers who see and listen tend to get the most information.

Yes - in part because their attention cannot be directed.

> The TV audience seems to be the next best informed.

I disagree. They get different information, that's all. They only see and hear what the TV director allows to be in the telecast. For example, if the camera is on Kennedy, the TV viewers can't see Nixon's reaction. The on-site viewers can decide for themselves who to look at - but if they watch Kennedy they miss Nixon and vice versa.

> Radio listeners get less
>information than the TV audience.

Not necessarily. Their focus is different. They are not distracted by the visual. Listeners get different information - they get info that the TV audience misses because TV viewers are distracted by the visual. Kennedy wooed the viewers in part because he looked better.

We like to think we are rational beings making objective judgements based on facts, but in many cases people are swayed by things like appearance and the sound of a voice.

Ever listen to "Prarie Home Companion"? They put together a true radio show. Seing videotapes of a performance causes one to miss the fine points of the performance.

"PHC" is a good example of the differences of various communcation modes. One cannot sit back and listen to it passively. Unlike TV, one has to be actively listening and visualizing the story in one's mind.

>Readers are deprived of the speech
>nuances, as are CW users.

True to a point - but readers have punctuation. And a reader sets the pace, and can go back and reread. "Live" communication happens and is gone (unless you rewind the tape). Different information entirely. Reading also forces the reader to mentally visualize what is being described, similar to listening.

Morse users have a piece of all of this, plus some distinct features. As used by hams, Morse is usually "live" and "aural" - so it's like listening and talking. Yet the sound and appearance of the people communicating are not a factor - only their skill in using the mode matters. So Morse becomes a great equalizer, eliminating prejudices based on accent, gender and age.

>
>If we want to communicate in place of a commute, shouldn`t we all use
>2-way TV to get fastest access to the most information? Bell always
>thought so, but never could sell it. Maybe the technology was still
>lacking.

The "Picturephone" was basically a form of low resolution SSTV. It couldn't capture motion very well. Plus it was so expensive that few people went for it. In other words, most of the info needed could be sent without the picture. Note how fast fax machines caught on, once they became inexpensive, as a way of sending visual information.

>CW seems best suited to a last resort.

I disagree. It's another tool in the toolbox, that's all. Like ASL (American Sign Language) which has unique features of its own.

The real trick is to choose the right tool for the job at hand.

Jon,
Take a look at the tuner on Rick Measures page (don't remember
the URL). He has a balanced tuner that's fairly simple.

I see this question asked here from time to time and the usual answer is to string up a wire antenna. That was a very good choice some years ago when there weren't MW stations jammed everywhere. Your best bet is a tunable, directional loop. I have one put out by Radio Shack and it works quite well with my DX 390 and just about every other MW receiver. It just sits next to your radio and inductively couples to the internal loopstick. It works quite well and is not expensive. About $30.00.

Dunno, I think I would find someone with a little more experience to handle all my important intellectual property. I would want no less than Perry Mason. But I do have a job I would be willing to trust him with. I wonder if he could find the lousy bastard that stole my brand new floor jack the other night? I'll sure make it worth his while. Have him quote me a fee if interested. I'm good in the book. MK

Based on my half century afloat in pleasurecraft plus some significant
experience with the Right Coast commercial fishing fleet (ignoring my six years
with the Naval Establishment, many days of that gig spent in CV/CVA radio rooms
during shakedown cruises) it doesn't take long to learn that if top quality
radios count anywhere they count most aboard small craft like 36 foot ragboats
in offshore blue water. A typical example of the kinds of radios the pros use
when their butts are on the line:

When you get gored by a 55 gallon oil drum piece of half-submerged flotsam and
it's going down fast bow first 'way offshore you better have a reliable ssb
radio and a backstay antenna that booms the USCG per Roy's comments and to hell
with whether or not you can work 20 with it.

No, you just haven't taken the right steps. Here's how to get up some interest.

1. Bend up some wire and call it an antenna.
2. Publish a picture of it in several magazines, and put a picture of it on your web site.
3. Make up a "figure of merit" from various characteristics which favor your antenna. Announce on this newsgroup that you'll give $1000 to the person submitting the design which beats your antenna's "figure of merit" by the greatest amount, claiming that no other antenna can. Declare that the "figure of merit" will be determined by antenna modeling, but refuse to publicly release a model of your antenna for others to use for comparison.
4. When someone accepts your challenge and makes his own model by looking at the pictures you've published (and also produces other models exceeding your antenna's "figure of merit" by a large amount), don't honor your public offer. Instead, deflect attention from the fact that the other antennas are superior and that you won't be paying the money after all by loudly declaring the other person's model to be your "intellectual property" and accusing him of stealing it from you. Increase attention by accusing and threatening anyone who helps others actually get this model. After all, it's in your interest to prevent others from seeing for themselves that the other antennas are better.

So you see, the wider range of things you claim to be your "intellectual property" and the more noise you make about them, the more interest you can get. Unfortunately, the interest won't really be in your actual intellectual property, but rather in the spectacle you make of yourself. But if it's attention you crave, and you can't get it by really coming up with something revolutionary, this is a tested and proven formula. Go for it.

Roy Lewallen, W7EL

-- Accused thief, pirate, and alleged and threatened, but
unconsummated, lawsuit defendent

Anyone who wants to look at Steve's MI2 model and his superior designs can download them from ftp://eznec.com/pub/MI2. (You can view them with the demo version of EZNEC, available from http://eznec.com, or run your own calculations using the standard version of EZNEC.) If you want to compare Steve's MI2 model and file with Chip's, first you've got to get a copy of Chip's file. Good luck.

1134. uhf/vhf/fm antenna ?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-13 03:20:47 UTC
From: whozix <whozix@hotmail.com>
Message-ID: <93ohif$b19jo$1@ID-44649.news.dfncis.de>
Source record: 172358
Cross-posted to: rec.radio.amateur.antenna,rec.audio.tech

Please forgive the dumb question but I've never done this before. I have an attic-mounted TV antenna with a coax downlink to a splitter, currently feeding two TV's. I would like to use this antenna for FM reception as well. I have purchased a three-for-one splitter and I have run a coax to the FM tuner. My question is, do I need any kind of special filter or can I simply connect to the FM antenna terminals on the receiver. If so, should I use a 300 to 75 ohm adapter or simply direct-connect the coax to the receiver terminals? The adapter has no discernible polarity markings but the receiver terminals are clearly marked for polarity - one terminal for antenna, the other for ground. I am within 10 miles of most transmitters and receive a strong signal that produces a good quality TV picture.
Thanks in advance for any advice and for you cynics, yes, I did a Deja search and read many posts, looking for this answer.

It won't hurt anything to try. If the receiver is marked antenna and ground, it is likely 75 ohm, and matches the rest of your installation. You may have to put an FM filter or attenuator in the line if the signals overload your receiver (stations show up at more than one place, two signals at one place where neither belong [intermod], etc.). This latter depends on the front end in the FM receiver, and is difficult to predict.

The other approach is to get a band splitter which splits the FM from the TV, run the FM output to the radio, and the TV to a two way splitter for the TVs. This may be difficult to find, as I don't think Ratshack sells one exactly like this. MATV sources have them. Still may have overload problems.

Source record: 172361

Richard Clark critiqued this discussion to some extent on style and substance. He is professionally qualified to do so. But, these are transient exchanges. They aren`t planned and edited for posterity. That`s my excuse, and I`m sticking to it.

No ham is likely to say we have plenty of bandwidth. We will always need more spectrum and narrower signals. It`s traditional. We will always need enough space to accommodate the peak traffic load. We live in a world that never sleeps, so our demand is 24 hours, 7 days, and 365 days a year, at least. We also need enough space to accommodate redundant transmissions so that data can be compared bit-by-bit to be sure there is no error.

Richard Clark also wrote:
"-you don`t have to be a conductor to appreciate and "understand" the language of music-"

Here, I beg to differ a little. Apprecation does not require an ability to conduct. To appreciate and understand the language of music as a good musical conductor does, likely requires the ability to read music, to know the challenges, and to imagine great possibilities for the music`s performance.

The argument that Morse is a language was in suppport of new uses for a mode which is fading from the scene in its traditional applications. It was just grasping at straws.

Best regards, Richard Harrison, KB5WZI

RF flows only on the skin of any conductor, the depth of the skin being a
fuction of the frequency. At 900Mhz you could probably use aluminum foil
tubing without suffering any losses.
>

> How about the boom - any electrical performance advantage of using

Gain is gain, receive or transmit. If you really wnat to do it right and
save yourself a lot of backyard experimentation you should consider modeling
the antenna with programs like EZNEC.

"They only see and hear what the TV director allows to be telecast."

Very true. Editing has always been able to shape the form and content of a presentation. I assumed an unbiased presentation, which is as unreal as a "lossless" transmission line.

Jim also wrote:
"Seeing videotapes of a performance causes one to miss the fine points of a performance."

Again, agreed. Beyond distraction, nothing can compare with the rich performance in the theater of the mind if you turn it on and let it loose.

I use foam 8X coax which is pretty flexible. The body of the center insulator is a
standard 75 cent filled nylon "dogbone" strain insulator with three molded-in
"disks & valleys". I wrap the coax tightly all the way around the middle "valley"
of the insulator with a four inch "tail" pointed down. I double-tywrap the coax

and tail together right under the insulator. Then I strip three or so inches of insulation off both the braid and the center conductor. The braid gets soldered to the end of one dipole element which is attached to one end of the dogbone and the center conductor gets soldered to the end of the other dipole element. Goop the exposed end of the coax to keep water out. Light, low profile, build nothing, two for a buck fifty.

The current version is 48, and is on a CD. It is a DOS/GWBasic program, but will run in Windows' DOS window. It is not available on the web, although older versions may be. You can buy it from VE3ERP for US$7.00, including postage. Murph (VE3ERP) donates all proceeds to a Canadian association for the blind, so your money is going for a good cause. You can contact him at ve3erp@encode.com.

Steve,
All kidding aside, I doubt if changing to ladder line
would be any benifit to you. There just isn't that much
loss in 50 feet of coax (unless it's really terrible
quality coax). Even at QRP levels the loss shouldn't make
a lot of difference, if all else is as it should be.

Peter O. Brackett <ab4bc@ix.netcom.com> wrote:
: Backstays as antennas...

: Safety of life at sea demands that one ensure sure that backstay antenna
: setups are first and foremost structurally sound and do not compromise the
: mechanical integrity of the backstays. Then, and only then, should one
: consider optimizing the electrical and electromagnetic efficiency of an
: antenna which is an "auxilliary" use of such basic structures.

Certainly. But a properly set up backstay for an antenna does not compromise
the structural safety of the backstay. Such antennas are, of necessity, a
compromise as far as radiation efficiency go.

: Lots has been written in the blue water sailing literature and periodical
: press about HF antennas on sailboats, some basic research by your friend is
: in order.

Such antennas have long been used for boats - and are well accepted.

: If the safety of life at sea is at stake, and one is going to [perhaps]
: compromise their marine safety by modifiying basic boat/ship structures like
: stays and or masts to accomodate an HF antenna installation, they should
: consult not only HF antenna experts, [i.e. like gurus in this news group],
: but also competent marine/naval architects/engineers who are qualified to
: design and "sign off" on the structural integrity of masts and backstays,
: etc...

I would not suggest that a person wing it on their own. While they can do
that on the grounding/counterpoise - as there are plenty of good articles
available, any modification to the rigging support must be designed by a
knowledgeable marine engineer/architect.

: Just a word of caution...

Thank you for the elaboration. I should have included the warning in my
original response.

> Then he hadn`t understood what he typed.

Correct - he wasn't even aware of what he had typed, per se,
only that he had typed what he heard.

> His keystrokes were
> "conditioned responses" to the unique sounds of Morse characters.

The exact same way a spoken sentence is "processed" from sound
to thought. Sound is, after all, vibration, not thought or ideas. Spoken
words are sounds. Audible Morse code is sounds. In both cases,
an idea is conveyed. One fluent in Morse - or English, Chinese, whatever,
can converse with another fluent in the same language with no translation.
You cannot think about an idea without using words. As you read this
you are not "translating" the individual characters, one at a time, into
English words. You are recognizing an image as a word - no translation.
But when you first learned to read, you had to translate. You saw
the image CAT on paper and had to work to bring to mind the furry
fourlegged creature that that image represented. In time, the image CAT
became part of your written language.

The same thing happens when you meet people for the first time. It
takes some time and effort to recognize that a man with a a particular
appearance is Paul Smith. Later on, there is no effort - you just see
the person and Know he is Paul Smith. No translation - the image
automatically evokes the recognition. That same thing happens
with Morse - you go through the learning process where translation
occurs. But if you develop fluency - the vibration that is sound
automatically evokes the idea that sound represents, just as the vibration
of light evoked the understanding that the person you are seeing is
Paul Smith.

Now, whether it is seeing a person that you understand is Paul Smith
thathear or hearing a tune that you understand is the 1812 overture,
or hearing morse that you understand as an idea, words are always
involved. Conscious thought requires words, but language does NOT
require words to meet definition number 2 in the American Heritage
dictionary: "2. A non-verbal method of communicating ideas, as by a
system of signs, symbols or gestures". Thus the system of audible
symbols which you hear as dah di di di di di at 5 words per
minute, and then translate, if you are still struggling to learn, is

heard as part of an overall idea at 50 wpm by one fluent in morse:
"The quick brown fox jumped over the lazy dogs back". The 5 wpm
translation process for the one starting to learn morse is something
like this: let's see, 1 dash by itself is the letter T. 4 dots together
is the letter H. One dot by itself is the letter e. THE

The 50 wpm man hears a blur of sound that carries a particular
meaning - he is not translating individual dots and dashes and spaces
into characters, then into words. The fact that he can hear
1000 ONO 15 with one ear while conversing with me in Spanish and
English, type 1000 ONO 15 on his machine and transmit with his other
hand all simultaneously proves he is using a language with no
translation needed for the idea to get across. See definition 2. The idea
communicated is that wind at 1000 feet is at 15 knots in a west north west
direction. The idea arrived in morse symbols and ended up on paper
in written symbols. I looked at the paper and did not understand what
it meant - he had to translate it for me. One column always contained
altitude, another wind direction, another wind velocity. The idea was
communicated, no words were used.

Hi Joe, if you have a balcony you might try these ideas I sent to another Ham,
I would look at this page
http://www.sgcworld.com/publications/stealth.htm
A "smart tuner" or weather proofed manual tuner, with 3/4" copper tubing built into a loop around your balcony might be your best solution. Another is a magnetic loop as in MFJ's 1786 (10m - 30m) or 1788 (15m - 40m). But your desire to work 40M, 10M, 6M, 2M, and .70M might rule them out. One thought is Yaesu's ATAS-100 small screwdriver, with the proper counterpoise (maybe a ground screen on the floor of your balcony, or radials cut for each band) this one antenna will cover all the bands you mentioned. Unless you have the Ft-100 or the FT-847 you would have to use one of the controller boxes available (ad in back of QST). Another idea is folded dipoles run along you balcony for the bands you want.
I personally would go with the loop-tuner combo with separate verticals or vertical dipoles built on to the inside of balcony for UHF & VHF. Also the best chances to reduce RFI to your neighbors would be to get the RF outside.
For more ideas check out my site at http://www.geocities.com/n0hc/.
Also a bunch of info found here..
http://www.dxzone.com/catalog/Technical_Reference/Antennas/

Some of us understand that life will sometimes take us to places that is not "ultimate" for Ham radio, but the dedicated make the best of it and even have fun with the challenge...

> at a slow baud rate.

Cecil, you are confusing the fact that conscious thought uses words
with language. Language is used to express thoughts and ideas and
emotions. When I see an actual tree, I use the word "tree" to express
what I am seeing. The actual communication (ie the process whereby
I became aware that the tree is there) of the idea into my thoughts did
not involve the word. The tree didn't say " TREE!" A combination of
vibrations of light evoked the thought. The same thing occurs in speech -
a set of audible vibrations evokes specific thoughts. We didn't see
"TREE!" but the result is the same. Now, when we develop a
system of sounds - spoken words - to convey ideas between ourselves,
we call that a language. Morse is a system of sounds we have developed

to convey ideas between ourselves. We have to train ourselves to
demodulate morse, so to do that we start slow, and break that language
down to REALLY small pieces. We then translate those pieces into
some intermediary form through a relatively slow process until we
recognize the individual letters T R E E and then translate that to the
word tree, which, once done, simultaneousley causes us to think "tree".
If we had to do the same thing with speech, it would take us a number
of years to become fluent. And we would have to do a LOT of listening,
before we could recognize a particular set of sounds as "tree".
But, the meaningless sounds a baby hears become language, over time.
And morse is the same. If one spends enough time, one develops
fluency in that language.

By that logic, French is not a language, because I don't understand it.
"If French were an actual language, then I would understand what
was being said, because it would have been translated to a language
(French) with which I am fluent". The key is fluency. When I get
fluent enough in French, I will no longer need to translate it to
English. The sound of the French word will evoke the idea, with
no translation needed. Fluent morse evokes the idea in our thought
without translation. The fact that conscious thought uses words
does not mean that specific sound cannot directly cause specific
thought. Thats how speech works. Thats how morse works, too,
when you are fluent in it.

I'd like to echo Richard a bit. I see no point in using larger antennas for AM BC reception if the antenna in the radio is decent. Normally, there is no need for any more voltage to the radio. If you add a big monster antenna for AM, all you really end up doing is pumping up the S meter. The signal to noise ratio should be about the same. Maybe even worse if the big antenna picks up more noise. I think a small loop probably the best way to go really. The only additional thing you need in an antenna for AM is directivity. The loop will give you this. They aren't planted on the old transoceanics by accident. They work. I think about as well as anything for real low freq BC. Even the ferrite rod antennas work pretty well. The small size is deceiving. It seems as some think because they are standard in the cheaper radios, they can't be any good. They usually do fine unless you are in a metal building or something. There are better antennas for the hard core, but much more work involved. I think an old transoceanic and the loop on top, hard to beat for listening to AM BC. BTW, the early 50's T/O had a better loop than the later 50's models. It was wider and a larger oval. The later 50's had the narrow racetrack looking loops. I don't think it works quite as well as the older one I had. "I had an early 50's model a few years ago, but now have a 1958 model with the narrower loop". I liked the older one better. MK

Dunno, I don't really think it's a language. The reason being is we are already sending a language. "english".
But then on the other hand you see "sign language" which is doing the same thing, sending english in a different form than writing or speech. Dunno, if "sign language" qualifies as a language, then I would have to say yes, morse is a language, but in my opinion , neither are true languages. But on the other hand, I do think high speed code operators DO utitilze morse in much the same way as a person would use a different language.
Mainly in the manner in which no real conscious thought is needed to listen to it. If someone says to you, pick up the telephone, you don't have to sit there for a second to think what all that means. It's automatic. To a fast code operator it's much the same. And there is nothing magic at all about it. It's just practice. Anyone can do it if they want to. Or I think anyway. It's no different than learning to type or anything else really.
I can go fairly fast because I've known the code since I was in the 8th grade. or 30 years. If I haven't got it down by now, I might as well hang it up...:/ Everyone else I know that has used code that long is fast also. Almost without exception. "The ones that actually use it , that is.." You gotta lose the pencil to really boogy woogy. I only write important stuff down. The rest I just listen to. Transfering it to paper is what will kill you if you really want to go fast. It's silly anyway. You don't write down "pick up the phone" , when they told you that...g There is no need for it for code either unless you just feel compelled. The main exception being a contest or traffic something where you have to be real accurate for records. I tend to pay a bit more attention in a case like that, but normal qso's I write only the name and callsign down. And the only reason I do that is because I'll forget em 3 min later if I don't...I also sometimes use a form of shorthand gibberish to keep track of what was said which of course is totally useless to anyone but me.. -o-0-o- MK

Hi Richard,

Morse will persist for as long as it is fun. Future contesting might find more points awarded for lower SNR (1:1.1?) or, say, working under a BBC broadcast might be the next challenge. If, is as offered, CW is the service that gets through when the going gets rough - well then CW should be the last service running after the lights go out.... if you have faith in the original argument ;-) It seems some of the logic appeals to the apocalypse to fulfil a prophetic CW legacy ("Ham Radio operators thwart sophisticated alien invasion with lowly morse code").

However, I am a sucker for tradition. Sport has its season, game, and distinctions in class of weapon. Regulation of the commons goes back centuries, millennia. Archery used to be compulsory practice, but now it is a sport with its own season.

The argument shouldn't be about how to preserve/take the CW Bands, it should be how to grow ALL the Bands. Open up HF to all comers. Make it easier than getting into CB.

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.shortwave

Hi,

Recently, I have been reviewing my home antenna system and I have
decided it is time for a change.

A friend mentioned to me that Delta Electronics make a wide band
antenna called the model RAS-10A which covers 1-30MHz, in a span of
only 40 feet. I believe it could be used for transmitting as well.

This antenna seems to have no traps and it isn't a fan type of dipole,
there are no loading coils or linear type of loading either. Instead,
there is a prominent "balun" in the center of the antenna, connected
to the feedline and the two legs of the antenna.

The question is how does it work? How CAN it work? I seem to remember
a few years back an antenna which claimed similar performance in small
size yet when it was checked out by QST it was really a short dipole
with a mysterious circuit board and a large resistor! It certainly was
50 Ohms at all frequencies but didn't radiate too well. I'm certainly
NOT suggesting the Delta Electronics antenna is like this though!

So does anyone have any experience of the Delta Electronics RAS-10A?
I'd be interested in your comments before I pursue the matter further.

Please reply to: tf.electronics@virgin.net

Given those materials and sealing it after it's tuned with something like RTV it should hold up for a very long time, decades probably. The only problem I can visualize might be getting the RTV to adhere to the Teflon.

> with language.

Nope, I'm not. I think in English. Objects aside, how does one represent an abstract idea like 'truth' without resorting to one's language? I cannot do it without the associated English word, 'truth'. - .-. ..- - .... is just a Morse coded representation of the English word, 'truth'. In fact, I do not think the English word 'truth' can be mentally avoided when one receives - .-. ..- - .... in Morse code, assuming one's native language is English.

ehsjr@bellatlantic.net wrote:
> Fluent morse evokes the idea in our thought without translation.

But there is a one-to-one correspondence of Morse characters to
English characters. You cannot convince anyone that the Morse
word - .-. ..- - .... does not evoke the English word for
'truth' in your thought processes. Only someone blind and deaf
from birth would be capable of attempting to think in Morse code.

For virtually 100% of the human race, one's native language is
firmly fixed in one's thought processes before Morse code is
learned. I think in English. When I hear -. .- -- . in
Morse code, I hear the English word-concept 'name' with which
I think. -. .- -- . is just another way of writing an
English word. 'dah-dit dit-dah dah-dah dit' is just another
way of sounding an English word.

Liz,

So you are building a modern version of the "Beer Can Vertical", an interesting project from the late 50's. It was written up as a project in CQ Magazine, if I remember correctly. You supposedly drank beer so why not recycle the cans! I was lucky, my father drank a lot of beer (over time) so I started collecting the cans and eventually tried my hand at building the vertical!

I used a 250 or 500 watt soldering iron, not a wimpy little pencil iron. I used rosin core solder. I could never get the thing over about 8 feet without having it break apart! I soldered around the cans completely at every joint. I can't remember taking off the ends. I can't imagine any problems with leaving them intact. The biggest problem I can see is that modern cans are made from Aluminum, not steel. You want steel cans if you are going to do the soldering!

Use some guy ropes or wires when you put it up. The Anne will be very heavy. It will be most prone to breaking while you are raising it!

Bob,

With receiving you are not worried as much about having a perfect match to the antenna. Most receivers have more than sufficient gain to compensate for a mismatch. However, when transmitting a close to perfect match is very important!

I had a 30 - 10 meter version of that antenna. Yes it was sharp, but I ahd their autotuner and it quickly found a match. Your operational success will depend on where and how you mount the antenna. If your mounting place is close to your station you will undoubtedly run in to problems with near field radiation causing all sorts of problems, like receiver blocking and transmitter hangs ups. If you mount it far enough away I think you'll be happy!

Curtis,

Your mount will depend on what kind of an antenna you want to put on it! For example, you wouldn't need much of a mount for a VHF whip, but you would need a much better mount for a HF Beam! There used to be a number of roof top mounts sold for hams and also for TV's. Check out the ham magazines like QST.

Source record: 172245

What you want is first to provide a decent ground for the antenna! You are using a vertical. As you have it now the antenna is unbalanced. A tuner will not balance a vertical antenna. Connect a piece of wire that is 1/4 wave long to the Vise Grip. There will be a screw on there especially for making a ground connection. Then add the tuner if the system is not tuned to the PSK20 frequency (high SWR).

Richard Clark, KB7QHC wrote:
"Open up HF to all comers. Make it easier than getting into CB."

I agree, and as Richard said: "Morse will persist for as long as it is fun." Morse need not be used in commerce or the military to be useful to hams. Amateur radio is non-commercial by law. CB may be unruly but it has no ARRL organization nor tradition of self-regulation. A large influx of new hams need not cause chaos.

Another concern expressed in this thread was band crowding. I wouldn`t expect all of the new hams to crowd into the 30m band with its tiny size and other limitations.

Most new hams are likely to be appliance operators. Heathkit is gone and the days of saving money by doing your own point-to-point wiring are just about gone too. It is hard to compete with offshore labor and automatic assembly.

Store-bought radios aren`t difficult to operate legally. When they aren`t operated legally, the operator can be notified and if the illegal operation persists, fines can be imposed regardless of the origin of the radio.

VHF occupancy could be improved by an influx of new hams. Plenty of cheap consumer electronics could be adapted to VHF ham bands.

Ham radio needs resuscitation and it can only be achieved by an influx of new hams. Morse has always inhibited growth of ham radio. It couldn`t be helped when Morse was the only game in town. Now, Morse is just a marginal player in the larger communications field. It`s long past the time to put it away as an entrance requirement to ham radio.

Best regards, Richard Harrison, KB5WZI

1172. Re: 10m mobile ant. advice

Justin,

An antenna can be resonant at only one frequency at a time. No antenna can exhibit resonance over the range from 11 meters to 10 meters! If your antenna cannot be tuned to 10 meters I would recommend taking it back! Radio Shack sells many good products, but also sells many compromise products.

Make up a decent antenna, a 10 meter dipole does not take up much space and is fairly cheap to build! It solves most of the problems you will encounter. A vertical has much more problems with installation. You will have to have a good ground plane at the antenna!

Bob,

The short answers to your questions are:
>
> 1) Can I hook up all the counterpoises at the same time, or if I can
> only have the one for the correct band hooked up at any one time?
>
Yes
>
> 2) I plan to run them all tie-wrapped together, is that OK, or do they
> need to be spaced?
>
They should be spaced apart. Running them together makes them look like
one big wire!
>
> 3) the counterpoises for the 10-20 meters bands will drop vertically to
> the ground, however, the lower bands will have to run to ground level
> then run along the ground. Will that work?
>
Yes they will work.

I should say that using an Outbacker as a fixed vertical is OK, but a
lot of the performance will depend on your skill!

Ray

Building a dipole in close proximity to the balcony railing is an exercise fraught with problems! You can't achieve enough separation of the antenna from the grounded railing to make it work! A better idea would be to mount a short FM vertical on your railing.

Paul,

Why not use the traditional end fed random wire solution? Run as much wire out as you can, and connect it to the rig through a tuner? Almost any random wire tuner will work. I have used this for 20 years now and can say it works. I have used tuners from a cheap little MFJ unit up to a Drake MN2700 with good results.

Oh, don't forget a ground radial at the transmitter! I use a short piece of wire running along the baseboard in the room and tune it through an MFJ Artificial Ground!

I think Cecil is exactly right. If you`re totally immersed in a foreign environment for some years, it`s likely you`ll switch off to the foreign language for your thoughts from time to time. You often may only be able to come up with the foreign noun or verb you seek to recall. At least that`s my experience. I doubt this happens often with Morse code. You want the word? Just decode the Morse.

Let's get one thing straight ... I can find my way around a computer, I can read the instructions for a radio - but after that it's all downhill. Technicalities in words of more than two sylabuls will cause problems.
So - I am thinking of upgrading my Alinco DJ-X10 Scanner to a Yaesu VR5000 Wideband receiver.
What in simple terms would be an easy to erect aerial, the main frequencies in use will Aero HF, Aero VHF, and Marine HF, Marine VHF - so we are looking at 2mHz to 170mHz.
I get the impression that a 'longwire' is probably the easiest. Is that what is is? Just a great big length of wire as long and as high as possible and just stuck into the receiver?

Open to offers and advice.

"Floyd Sense" <sentek@sprintmail.com>
shared these priceless pearls of wisdom:

Floyd --

I'm sorry, I didn't see your first post, so I don't know if you are talking about a 12' Sunfish or a round-the-world class vessel.

I had a Cat-22 for a whole lot of years, and while I took her bluewater a few times, most of my sailing was freshwater. However, I *did* enjoy the TS-130 rig while moored out overnight, and my solution was to load the aluminum mast (with all the attendant rigging electrically connected to it). and use the swing-keel as the ground. There was enough water leakage into the metal keel and draw cable that I got a fairly consistent performace from this lashup.

There are (memory fails me now) about a dozen through-bolts into the cabin area that hold the mast to the rest of the superstructure. I just made damned sure that the one I chose to attach to was making good electrical contact with the rest of the aluminum mast.

Hope this helps.

Try commercial hot glue for weather proofing your capacitor. I use hot glue all the time for my outdoor weather proofing requirements. A heated blow gun will undo your seal job very nicely if you ever need to open it back up again. I have one application that has been sealed for over 7 years now without any evidence of leaking. 73, Ed - N5NUG

Actually, a physical dipole is resonant at 1/2WL, 3/2WL, 5/2WL, etc.
A standard G5RV antenna system is resonant on 80m, 40m, 20m, and 12m.
My 120ft dipole fed with 88ft of ladder-line is resonant on 3.993
and 7.216 at the same time.

The charge today can be up to $10 per fcc regulations.
The limit is $10 though. It was $6 when I got mine 7 years ago roughly,
course that VEC didn't charge the full rate, I think the max they could
charge was $7 or something.

Has any one tried the Spiro endfed slopers? The vs-53 does 10-80 meters at 42' long, and the vs-64 does 10-160 at 73'. How is the bandwidth.

Bingo. But also: Use a couple of SS "hose clamps" from the hardware store in addition to that "double-tywrap" to strengthen the coax connection to the dogbone.

To avoid soldering in the field, just use 1/8 inch wire rope clamps (tiny "U-bolts") to secure the coax leads to the dipole wires. Works for me.

I built one of Cecil's 130 foot ladder-line fed antennas, and I get THREE band operation with about 95 ft of "450" ohm LL. Operation on 21.1, 7.1, and 3.9 MHz, all SWRs down below 2:1 with no tuner.

VF of LL can vary, so I cut the LL to tune the antenna with a MFJ259B at the end of the LL

Principles are discussed on Cecil's page at:
http://people.delphi.com/cecilmoore/mystery.htm

Mine is about 50 feet high. I will build the relay box someday to switch in the additional LL to match other bands as well. Great antenna.

That's the beauty of this antenna system. Add 8ft and get 30m, 17m,
and 10m operation. I fear that I have failed to convey the advantages
and simplicity of this system. In particular, hams with built-in auto-
tuners can bring this antenna into their auto-tuning range quite
easily. In particular, hams with fixed tuned 50 ohm amplifiers can
get by without a QRO tuner which was my incentive. If one has to
have a feedline, why not let it do all the work?

Having spent 35 years in the Marine electronics business and a portion of that time with the FCC as a field agent mostly doing SOLAS Inspections, I feel qualified to make the following comments.

Sailboats with Plastic (Fiberglass) or Wood hulls make the worst transmitting platforms afloat. The problem is rarely the antenna design or implementation, but the attention the installer paid to the ground system, that supports the antenna. Salt Water is one of the best RF Gounds that God designed on this Earth. The problem comes in trying to couple the radio system to the water, without electrolysis causing every bit of metal to disappear before your eyes. If you folks would just put on your "RF Filtered Glasses" and take a look at what the vessel looks like at RF, it would be plan as the nose that holds up those "Glasses" that what is required is a good coupling into the water. Plastic and Wood make great insulators, and therefore you can't see them thru you "Special Glasses", so now that we are really trying to see what available, lets take a look. You see, the engine, the shaft, the prop, the keel if it is metal, the chainplates, the mast if it is metal, the rigging, if it is metal, the rudder and rudder post, and the tanks if they are metal. Now just how is RF coupling going to be induced into the water, well by capacitive coupling of course. Of course in a metal hulled vessel this is no problem as the hull makes one plate of the cap, and the water makes the other plate, and the paint is the dielectric between them. On a plastic or wood vessel, The hull is the dielectric, and the water oif course makes one plate. The second plate you build, as your grounding system. Lower Impedance is better, than higher impedance, so how do we build a bigger or better coupling plate for our side of the cap?????? Well there are two things that increase capacitance, more surface area and closer coupling. Getting more surface area is done by tying every scrap of metal together with low impeadance connections, or as some have said, glassing in copper screen to the inside of the hull, with lots of SquareFeet. Closer coupling is getting all the metal that is closer to the water bonded. It does no good to put your screen in the overhead of the cabin, or some such places, as it is to far from the other plate of the cap to be a low impedance at RF.

End of lecture: RF Gound Systems for MF and HF Maritime Radio System 101.

It is the GROUND System folks, not the antenna. A wet noodle will work quite well as an Antenna, if you got a GOOD Rf Ground. This isn't Rocket Science, it is plan and simple General Class Level Impedance Theory.

A good post, Bruce, but there is a better way than trying to
establish a "ground" inside a fiberglass boat. Instead of using
the backstay as a 1/4 wave vertical worked against ground, install
a conventional dipole vertically from the masthead. For 20
meters, it will be about 33 feet long, fed in the middle, and most
sailboats of the type mentioned in the original post will have a
mast longer than that. The presence of the mast will detune it
somewhat, but a competent ham or professional installer can
compensate that without too much trouble, and then you will have
an antenna with no ground coupling problems and no electrolysis.
If you're clever, you can probably make either of the port or
starboard stays the antenna.

If you're putting them into a lawn or other grassy area, you can just stretch them out on top of the ground, working them down into the grass. I use a bent wire "staple" here and there to keep the wires down where the ground is lumpy. Within a year, the grass shoots cover the wires. In the meantime, you can mow over them. (My soil is clay, so the wire "staples" -- made from galvanized fence wire -- work well. In sandy soil, you might want to think of something else. I wouldn't want a staple to work loose and get thrown by a mower.)

I have a 32ft rotatable dipole fed with 300 ohm ladder-line that works
well on 20m, 17m, 15m, 12m, and 10m. If made fixed and out of wire instead
of aluminum tubing, the cost is about $20.

OK, fine. You agree that jamming with Morse is virtually unknown in ham radio.
Works for me.

> It would be a waste of time.

That has never stopped you before, Cecil.
>
>> > Morse code tested hams
>> > use their Morse code keys to jam other hams.

Nope. You don't know what they used unless you were there at the jammers'
locations.
>>
>> That doesn't mean they were using Morse. You just want to badmouth the
>> mode.
>
>I've already said they didn't use Morse code.

I must have missed that part.

> I am certainly not badmouthing
>the mode.

Not right now, no.

>I am badmouthing code-tested hams using Morse code equipment
>to jam ham frequencies.

First it was "keys", now it's "equipment". Changing the boundary conditions is
not allowed. "Keys" are a small subset of "equipment".

What about others? How do you even know they are hams, let alone Morse-tested?
If they ARE hams, they're also theory- and regs-tested.

It's interesting that you say you are badmouthing Morse-tested hams who jam.
What about others who jam but are not Morse tested - guess that's OK with you?

> What is it about a string of 'dits' or a
>string of 'dahs' that you do not understand?

What I don't understand is how you know what sort of device was used to
generate the pulsed signals you claim were jamming.
>
>> >I have heard it.
>>
>> But have you SEEN it? If not, how do you KNOW they were using "Morse
>> code keys"? A simple 555 circuit will generate a pulse train for such
>> purposes. Computer software can do the same. A tape recording played
>> into a mike will do as well.
>
>Of course, a ham is going to whip up a 555 circuit to send a pulse
>train when he has an electronic keyer sitting there on the desk - or
>program a computer or play a tape recording.

Probabaly not. But how do you KNOW he has an electronic keyer on the desk?
Those things can be quite expensive - a 555 circuit is dirt cheap. Unless you
know who the jammers are and were present at their stations, you don't KNOW
what was used. You just ASSUME. And we all know what happens when one ASSUMEs.

>Give us an ever-loving break, Jim.

My unrelenting and irrefutable logic must be quite wearing upon you, Cecil.
Slow down. Take it easy. Relax. Put your feet up and run some antenna
simulations. Read some Ayn Rand. A is A, you know.

>You are just blowing smoke.

Nope. I leave that to the masters of smoke-blowing.

>> Point us to the NALs. Otherwise you're just blowing smoke and
>> badmouthing.
>
>Look at the NALs issued to code-tested hams for jamming.

Yup - lots of 'em. Awful. Guys oughta be ashamed. But they didn't use Morse to
do the jamming.

>I've have personally heard them using electronic keyers to do their jamming.

You have personally heard jamming - that part I'll believe. The use of keyers
is an assumption on your part unless you were there at the jamming station.
Maybe you WERE there, maybe not - I don't know. But don't expect me to accept
your assumptions as fact.

>I'm sure you have also and refuse to admit it.

Nope. I don't spend much time listening to the 'phone bands. Morse is my mode -
I'm on 40 meters mostly, with 80 and 20 as options. Lots of fun. What jamming
I have heard in the 'phone segements was done other ways. One common method was

to transmit some sort of weird wideband signal on top of the station being jammed. Sounded like some sort of noise generator - but I don't really know. Another method sounded like a dead carrier being wobbulated up and down a few kHz - I don't know how that was generated either. Playing music (a violation in itself) was yet another method.

Way back in the '70s there was a "jammer" that became known as the "woodpecker". Sounded like a string of dits with a terribly light weight ratio (on-time was about 10%) and a very bad case of key clicks - dern thing took up dozens of kHz or more. Some nut with a bug? Nope - a Soviet over-the-horizon radar system. Violated all sorts of international regs, but they did it anyway.

>
"Theater of the mind" - excellent! Exactly what I'm referring to. But the
theater of the mind requires the active participation of the audience.

The basic point was this: One form of communication isn't necessarily "better"
than another just because more raw information is delivered. A book can do
things a movie or TV cannot. A recorded/edited presentation can do things which
are impossible in real time. Morse can do some things that other modes cannot.

All of them are different tools in the toolbox.

A lot of transceivers have electronic keyers built in including inexpensive
ones like my IC-706 - no 555 required - just a key.

> >Look at the NALs issued to code-tested hams for jamming.

1215. Pi-L PA Output Network Design

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-14 02:25:52 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <93r3g8egq1@plutonium.btinternet.com>
Source record: 172190

NOW AVAILABLE:

NEW Program "Pi_L_NET.exe"

Pi & Pi-L OUTPUT NETWORKS FOR RF POWER AMPLIFIERS.

The program is in two parts. For given RF power output, RF plate/anode/collector volts and external load resistance, the first part computes either the L and C component values of a Pi-L network or of a simple Pi network.

The second part allows the L and C values to be varied in fine increments while observing how the input impedance of the network varies. The network input impedance is the load presented to the amplifying device: triode, tetrode, bipolar transistor, FET, etc.

In particular the input impedance can be observed as the tune and load capacitors are varied as in an actual amplifier. Or as frequency is varied off-resonance up to harmonics of the carrier frequency.

The program can also be used to compute L and C component values of Pi or Pi-L impedance matching networks between any two resistances. The phase delay through the network can be specified if needed for particular applications.

File size = 50 Kbytes. Download from website below in a few seconds. Not zipped up. Run immediately. Absolute bargain.

Thanks.

1217. Tower advice

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-14 02:56:16 UTC
From: wombat <chingada_madre@hotmail.com>
Message-ID: <kz886.171329$I5.4068930@news1.rdc1.sdca.home.com>
Source record: 172191

I am contemplating my first tower purchase. I would appreciate any pointers.

I am in Southern California, so wind is really quite mild and no ice, and I also have a lot big enough to give me 100 feet from the next door properties both sides. If I go up to about 85 feet or so, I have a clear shot to the Pacific Ocean, so I would like to get up fairly high, assuming that going to the height needed for an Ocean view is doable. I am in an area (San Diego County is the local authority) without tower height restrictions (as far as I know).

How large will the area on the ground be for a self-supporting tower 85 feet or higher? I want to put up a big interlaced yagi or quad (at least 4 elements on 20M), in addition to using the tower for slopers as well (if possible).

Also I need to be able to work on and replace the antenna frequently, as most antenna work I do is "experimental" and my antennas are usually homebrewed.

I have about $5K maximum to spend on this outrageous extravagance which I have promised myself since I was a fourteen year old novice.

Is 85' reasonable? Should I, can I? go higher in a self-supporting crank up?

How big is the "footprint" on the lot? Should I locate it away from the house (and nearby large trees) or keep it close to the shack to shorten cable runs?

All advice welcome.

wombat

I should also mention the following:

I am primarily interested in the short path to VK/ZL on HF. Hence the westward ocean view is important to me.

I would welcome recommendations on specific towers and brands, as no matter how much I read, I can't seem to understand how to calculate wind loading or find the cost of everything from tower to rotator (my budget includes for an allowance of $750 - 1000 for a really good rotator, so tips there would be appreciated also).

thanks

From: jflanders2@home.com
Message-ID: <3a6128dd.176131563@news>
Source record: 172199

Took some dipoles down a week ago after about 12 years in the air. Some rusting on the un-galvanized thread parts, but no disabling corrosion anywhere on the 1/8 inch cable clamps (I used cheap galvanized ones - you can also get SS ones at 5x the price). Some of them still had the black PVC tape I had put on them 12 years ago for UV sunlight protection, some did not. I put these clamps back in the air with new dipoles, feedlines, and supports.

My dipoles stay up a long time because I use farmer's steel fence wire 12.5 gauge to support the solid copperweld antenna wires in the trees. Some of the steel supporting wires have grown into the tree branches and can't be lowered anymore. Rope would have deteriorated long ago/

By the way, I had used some of the white plastic dogbone insulators on some of these and the insulators are still usable after 12 years, though flakey on the surface.

> > with language.
>
> Nope, I'm not. I think in English.

No Cecil, you don't. You "think in English" but you
do not think in English. According to scientists, you
think in vibation - some frequency of electrical energy -
and chemical activity in the brain. Now, lest there be
some debate about that, consider the following, which
demonstrates that thinking occurs when no language
is present. Thus it does not depend on what scientists
say.

That process - thinking - happens long before you
learn a language. If it was not possible to think without
language, then a baby could not learn.

You express - to your self, or to others - your thoughts
using language. But the actual thinking does not require
language. In communication, some external stimulus causes
us to think about the stimulus. It could be sound, touch,
scent, taste or sight which stimulates the thinking in communication
as well as othjer things. And that thought can start without
any English - or other - word. When alone in a room, The thought
that "it's too cold in here, I'd better turn on the heater" does not
start
with words. In the example I have in mind, it starts with your senses -
you feel cold. A person deaf from birth can think without a language.
For example, show them a light switch and demonstrate its operation.
They learn that the switch turns on the light.

A baby, with no language, recognizes love. It knows who its
mother is, without language. This proves thought, without

language.

uh-oh.

>and as Richard said: "Morse will persist for as long as it is
>fun."

That I agree with.

>Morse need not be used in commerce or the military to be useful to
>hams. Amateur radio is non-commercial by law.

Agree again!

>CB may be unruly but it
>has no ARRL organization nor tradition of self-regulation. A large
>influx of new hams need not cause chaos.

A large influx of newcomers who don't follow the tradition of self-regulation
WILL cause chaos.

>Another concern expressed in this thread was band crowding. I wouldn`t
>expect all of the new hams to crowd into the 30m band with its tiny size
>and other limitations.

Of course not. Yet during much of the sunspot cycle, many of the amateur HF
bands are useless for skywave propagation during much of the day. Those which
are useful get crowded. And the long distance nature of an open HF band means
that one's signal may be heard over millions of square miles. End result is
that crowding is a real concern.
>
>Most new hams are likely to be appliance operators.

Sure - because they don't know any better.

>Heathkit is gone and
>the days of saving money by doing your own point-to-point wiring are
>just about gone too. It is hard to compete with offshore labor and
>automatic assembly.

Yet it can be done, and is being done. See

http://www.elecraft.com

for an example of an under-$1000 rig that performs like it costs several times as much. And not only can it be home built, but with a minimum of test gear it can be aligned and repaired. And modified.

>Store-bought radios aren`t difficult to operate legally.

Neither are homebrew ones. Or kits.

>When they
>aren`t operated legally, the operator can be notified and if the illegal
>operation persists, fines can be imposed regardless of the origin of the
>radio.

Sure - but the violation shouldn't happen in the first place. We hams have a lot of freedom in our operating privileges. With that freedom comes responsibility.

>VHF occupancy could be improved by an influx of new hams. Plenty of
>cheap consumer electronics could be adapted to VHF ham bands.

That's what we were told in 1990. Didn't happen. The growth in ham radio in the ten years following 1991 is almost indistinguishable from the growth in the ten years preceding.
>
>Ham radio needs resuscitation and it can only be achieved by an influx
>of new hams.

What needs "resuscitation"? What type?

>Morse has always inhibited growth of ham radio.

Morse? The mode? How?

Do you possibly mean the TEST? If so, please say so.

The Morse tests were reduced to 5 wpm back in April - yet the number of US hams has grown by only 4,000 since then. That's about 1/2 of one percent.

>It couldn`t
>be helped when Morse was the only game in town. Now, Morse is just a
>marginal player in the larger communications field.

It's certainly NOT a "marginal player" in HF/MF ham radio, though.

>It`s long past the time to put it away as an entrance requirement to ham
radio.

It's just about gone now. The FCC has said they can't reduce it any more until the treaty changes. The whole debate is over a moot point.

The real causes of slow growth in ham radio have nothing to do with Morse or any tests. But those problems are a lot tougher to solve.

>the
>center conductor gets soldered to the end of the other dipole element. Goop
>the
>exposed end of the coax to keep water out. Light, low profile, build
>nothing, two
>for a buck fifty.

As usual, W3RV clearly explains more in a paragraph than I do with four-five paragraphs and a crude drawing.
>>
My PVC pipe design was derived from the "coax around a dogbone insulator" idea. Both have their advantages - I went to the pipe because it was on hand after making coax traps. It has the advantage of being easy to use in an inverted V situation.

One thing to watch with both designs is how sharp a bend you put in the coax. All coax types have a "minimum bend radius" spec - if you bend 'em too sharp, the center conductor tends to migrate off center over time. Problem is worst in hot climates with foam coax.

I first saw the idea in an old QST article (about 1957) by Lew McCoy, W1ICP (SK). He used a ceramic insulator!

Tywraps and lots of goop are the way to go. Hose clamps may squeeze the coax too much. Be sure to use black UV resistant tywraps - I've had the plain white nylon ones fail after several years in the sun. I just solder the connections - Brundys (split bolt electrical connectors) cost too much.

Enough PVC pipe for a pair of traps and a center insulator cost me about forty cents.

Here is what the dictionary thinks:

sign language n. 1. A language that uses manual movements to convey
grammatical structure and meaning. 2. A method of communication, as
between speakers of different languages, that uses hand movements and
other gestures.

You are still not separating the idea of what thinking is from
the use of language. Your observations are correct that you
learn your native language before morse, and that you can
become fluent in something other than your native tongue
where you "think in" that language.

I've experienced morse fluency, and you don't believe it.
If you haven't experienced morse fluency, perhaps you
can't understand examples oriented towards it. Lets try
a different area, not dealing with communication, but
dealing with thought.

Experienced runners can relate to this. I used to run 70
miles per week. I discovered that I could tell you my
pace within 10 seconds per mile, without looking at a
watch and without having consciously thought about it.
And I found that many other runners could do the same.
The really interesting thing was that this held true, even
if I was going at a MUCH faster pace than ever. From
time to time on training runs, I'd run cross country to
a high school 1/4 mile track and run with someone who
I'd never met. I would guesstimate my pace and then ask
the other guy what pace we were running. The most
impressive to me was when I ran with a guy and thought,
"Wow, we're doing a 6:10 or 6:15". My normal training
runs were, at the time, 7:30's. I asked, and he said "about
6:15". Now, how did I know the pace? I had not experienced
that pace before. True - we both could have been wrong.
But too many times I would run a street route I had never run
before, get back to the house, and know exactly what time
it was to the minute. That worked when i was running 8's,
9's, 8:30's etc. And when I later on drove the route to clock
it on the odometer, it always turned out that my pace, the
distance, and the time consumed all agreed with one another
mathematically. There is thought there which somehow ran
"the clock in my head" with no English used. The use of English
occurred only when I consciously thought of the time.

If the running example doesn't work for you, how about
music? A musician learns to play the piano at first by
consciously thinking about where to place his fingers,
and consciously translating the symbols on the sheet
music to letters - like b flat - and then pushing the
corresponding key. But an accomplished pianist
"thinks in music" and plays the instrument to make the

music come out. In jazz, the musicians communicate
a theme and follow each other. No words, just
sound. They don't even need sheet music.

Or how about catching a ball on the run? No English,
but some kind of thought where you adjust your speed
and direction to put you at the place/time coordinates
that enable you to catch the ball. Or observing a
person running to catch the ball - we arrive at the
opinion that he will or will not arrive at the proper
space/time coordinates to make the catch. We
"figure it out", without "thinking in English". We
express the result of that "figuring" in English, to
ourselves or others. But the figuring took no
English.

Your examples are trivial. Of course, some thought can be
accomplished without a language. My dog can do that. But try
abstract conceptual thought without words. How do you think
about 'truth' without resorting to the English word for 'truth'.
Don't know about you, but I find it impossible to think about
'truth' without referencing the English word 'truth'.

you are missing the help for the gentleman's request.
Lots of ways to make a dipole, full length, or trap shortened, even a
coil in the center.
Typically a dipole is fed with coax and a balun, matching the impedances
either with the coax or the balun being a transformer as well such as
4:1, 9:1 etc. also, parallel line is used, typically 300 ohm, or 450
ohm, and matched with a transformer etc. Some dont match, and use a
tuner at the shack to compensate.
A good suggestion is to get a copy nof tha ARRL antenna book and study
up.

You won't have to worry about ice but there isn't anywhere in this country which hasn't experienced very high winds at some time or another, assume 100mph. It only takes once. Your building code might have some requirements along these lines. An informal chat with your County Engineer would not hurt.
>

>
I think you'll find yourself a tad short of funds for a self supporting carnk-up which will handle big HF beams at 85 feet, but $5k should be more than enough for a guyed tower and perhaps a non-crankup.
>
Tune http://www.texastowers.com/, check out the Rohn, Trylon, Universal and US Tower pages for a first pass at catalog tower info and pricing.
>
Is 85' reasonable? Should I, can I? go higher in a self-supporting crank up?
>
With certain exeptions higher is better. Can you or should you are not a technical or operational matters, it's a personal judgement/budget call only you can make.
>

> How big is the "footprint" on the lot?

>
Big variable dependent on the specific tower and the tower manufacturer's required minimum base size for that tower. I used one cubic yard of concrete for my 70 ft guyed Rohn 45 tiltover. A buddy of mine had 70 cubic yards anchoring his 100 ft. Lingo pole. Whatever else you do don't decide you can get away with a base which is smaller than the manufacturer recommends.
>

> Should I locate it away from the house
> (and nearby large trees) or keep it close to the shack to shorten cable runs?

>
Locate the tower where it won't hit anybody's home if it flops over including yours. Run a single length of virtually lossless hardline to and up the tower and use a remotely switched Top Ten relay box at the top of the tower to select specific antnenas.
>

> I am primarily interested in the short path to VK/ZL on HF. Hence the westward
> ocean view is important to me.
>
>
You don't need to actually see the Pacific Ocean from the top of the tower to reliably work VKs and ZLs. A reasonably clear shot toward the ocean at any angle, say around five degrees up will work just as well as being able to see the horizon on the ocean from the top of your tower.
>

> I can't seem to understand how to calculate wind loading

>
Best illustrated by an example: Assume you have a ten foot long length of 2.00 inch diameter aluminum tubing as an element or boom. Ten feet is 120 inches. Multiply 2.00 x 120 and you get 240 square inches. Divide that by 144 square inches per square foot and you get 1.67 square feet of projected wind loading surface for that particular element. To determine the worst-case total wind load on the complete installation you add up all the projected square feet of all the elements, booms and the mast. In the case of continuously tapered quad spreaders determine the average diameter and multiply that value times the length of the spreader.

Max,
The feedpoint impedance of the average dipole is some
where between those two values, depending onhow it is
erected. For a single band dipole, I wouldn't bother
with a balun, they just aren't needed. For the lower
HF bands baluns are more of a problem than they are
worth.

William,

The gentleman said "I would love to have a multi-band but space will not
permit so I have to say single band. Resonant for say 3750 or 7100".
Regardless of your explanation of dipole construction, transformers and such
I don't see how any of these impact having room for a 80 meter antenna but
not having room for the exact same length 80/40 meter antenna. How will
getting "a copy nof tha ARRL antenna book and" studying up resolve why you
can have room for an eighty meter single band antenna but not for an eighty
and 40 meter multiband antenna that is the exact same length? Is it mirrors?
Reflections off the snow? Can you lower yourself to my level and try and
help me out William or do I need to read a book instead?

HUH?

Glenn - KB7PKC

I seal with molten solder too. I was just curious, always having felt wires twisted, clamped or what ever are going to have the surface get ugly without sealing it somehow from air and moisture. Solder seems to be a good wire sealant. :-) Obviously the clamps work, so to each his own.

If you cut it for one band 75 meters use coax direct to feedpoint, RG8 or 213. By the way it should work on 10 meters with low swr somewhere in that band. If you want the single wire dipole that you can use for more than one band use 450 ohm ladder line and an outboard antenna tuner. We can go into cores, baluns, chokes, feeds and reason etc. but it's not necessary. I would assume if cut for 75 meters it will not be above 60 feet in height (best) most hams only to mount 35 to 40 ft.

Good luck.

Hello All:

Looking for a reference book or web site that explains what is required for a insulator in a antenna at HF to VHF Frequencies to properly design a insulator (materials, spacing, and break down or arc voltage distances) to withstand high RF voltages, weather, ect.

My searches show a few clubs that collect old telephone pole insulators.

Thank you.

Jay in the Mojave

Hi Jim,

Being "for or against" is one thing, observing it is the reality of
the current situation is another.

Yes two classes would promote the sense of an equipment operator.
That is the point - there are MANY equipment operators out there who
are total devoid of what Rick calls "RF-Curious" (insofar as the
physics goes) and yet they manage to enjoy themselves nonetheless. I
very much doubt that any of them would take umbrage at occupying a
lower caste position (and I am sure they would probably infer quite
the opposite). As the current caste system exhibits many levels, I
cannot see the objection to fewer layers and a truer sense of
demarcation that is technically based (rather than a aggregate of

meager answers to a few lame technical questions, a few ace-buster rules, and a CW degree).

And you better believe I would reserve the technical privileges to those who have the necessary skills (from anywhere), or who wish to obtain those skills from others than the equipment operators (many of whom have "opinions" on the subject - we find many of their postings here). That was the whole point to amateur radio in the first place, but life has moved on, and there are FAR MORE who would prefer to just get on the air and talk - I support them heartily and I don't want them dinking with the equipment. I also see a need to recognize Technical authority, and for it to be assigned to those who are technically competent. The current regime of testing and classification has been turned into an ego reward for time on the air. Any similarity between the honorific of Advanced or Extra and technical competence is just that, a similarity - and a hollow one at that.

If, as you aver, that service is key, then having aknowledged Technical experts rather than the current system of multiple choice injuneers would be a true service to the Operators indeed (and to the greater community as well). The perpetuation of a broken and impotent classification system just won't do.

Opposition is the American way, but status quo is the way of the dinosaurs. All may oppose my suggestion, but if no alternative is offered to BOTH my suggestions AND the status quo; then the objections are transparent and have no basis to build a future.

Simply voting no is the signature to a suicide note.

I can't say for sure but if it works with a long wire then it
should work with a G5RV. But don't expect very good performance
out of the G5RV except on 80m, 40m, 20m, and 12m.

I cannot conceive of an abstraction without a word and/or definition
for the abstraction. How the heck can one conceptualize the abstract
notion of 'truth' without a definition for the abstraction? 'Truth'
is not like a rock. You cannot hold a truth in your hand to show
someone what you are talking about. Please rise above the solid
object stage of human thought shared by higher mammals and take a
look at the nebulous abstract stage that defines Homo Sapiens.

How the heck can you have a thought about an abstraction before
you have a definition of the abstraction? Truth doesn't satisfy
the identity of truth without a definition. For instance, try
thinking about the difference between 'truths' and 'facts' without
a definition of the two concepts. It is impossible. When a person
reaches a certain level of thought, it is impossible to think
without words, at least for me.

Keith,
There really isn't any 'cut-n-dried' way of doing
this. Usually, a ground or counterpoise isn't to 'picky'
as to it's shape, or how it's run. You just run it how
ever you have to. If it doesn't work as well as you
think it should, try a different way of running it. You
shouldn't need a wire as heavy as you have, but it will
certainly work. Good luck...

Have to agree with Ralph. I have used the wooden closet rod inside a piece of Schedule 40 PVC for many years on various antennas with no problems. Had a 7 element 2M and 14 element 440 mounted on piece and it withstood many a Montana winter and winds in excess of 60 miles per hour. Not sure how long you can make it before it becomes a problem but have had many in the 5 to 6 foot range with no problems what so ever.

>There is no crusade against the mode.

Yes, there is, Cecil. There are folks who want the Morse mode itself to die out, either by eliminating the available spectrum for it or by an outright ban. They are a small minority, but a vocal one. These anti-Morse people must not be confused with those who are simply anti-test, like yourself. They actually make the goal of the anti-test folks harder to reach.

> There is only a crusade against the outmoded requirement.

Would that it were so. But I have read enough anti-Morse (not just anti-test) diatribes over the past several years to know the difference.

It certainly is. Neither activity can be accomplished without
sufficient training and practice such that one can properly perform the
necessary functions to successfully complete the task. Some things
cannot be accomplished by "winging" it.
```

I mentioned "thinking in" music, and specifically mentioned jazz.
The "language of music" I had in mind was not intended to be
related to "sheet music language" to the exclusion of actually "thinking
in" music with no sheets, no visual image, just music inside the musicians
head, so to speak. A good jazz combo uses no words, no speech,
nothing but the sound. Jazz musicians create a theme and others
pick up on it and follow along. They are "thinking in music". No words,
no translation, just communication via the music.

As to loose definition - I gave the url and the definition I referred
to from Websters. You choose to dismiss Webster's, definition
as "loose". What do you offer to back up that contention? Perhaps
Webster's dictionary states that any definition other that definition
number 1 is a "loose definition" and can be dismissed as "loose".
If you can show that, that would effectively back up your point.

Both you and Cecil elect to dismiss anything that does not fit
into your preconceived ideas. The whole concept of abstract
thinking which Cecil brought up, while fascinating, has nothing
to do with the language of Morse. The concept can be
communicated via morse from one operator to another, without
the second operator thinking of it at all. He can be unaware that
the word was communicated, until he reads the printed copy
of what he typed. No English was involved, and no abstract
or conceptual thinking - until the operator read what he himself
typed in response to the sounds hitting his ear.

The point of that goes right to the original incorrect
assumption - that all Morse communications require a
translation - that Morse was only encoding English (or some
other spoken language). When fluent in Morse, and paying attention,
the sound directly evokes the concept in ones brain - there is no

translation. When not paying attention, the sound evokes, as an
end result, typewritten characters on paper. Again, no translation.
That is exactly how spoken English works. The sound evokes
the concept in ones brain, with no interim translation.
Neither you nor Cecil has been able to refute that. There is NO
difference, at Cecil's "30,000 foot level" - the sound strikes the
eardrum and evokes thought. And it doesn't matter whether
it is the word truth alone, or the word truth along with the concept.
One can read or listen to English, and repeat the words, without
pondering the abstract concept. For example, you can relate
what someone said to you as follows: He said "that's the truth".
Or you can ask someone the question "how would you define
the word truth - what does it mean to you?" In the first case,
there is no thought of the abstract concept of "truth" - you are
merely relating what was said. The second case is intended
to bring the abstract concept into focus.

Finally - a question: Are you engaged in this solely to
try to argue against a differing view, or are you considering
the other point of view, deciding it is incorrect, and then
arguing against it? For my part, I have tried to consider
what you and Cecil have said to try to understand your
point of view. I concluded a couple of posts back that it
might be that you and Cecil could not understand that Morse
is a language at high speed, due to not being fluent in it.
Thus the departure in other areas, including the scientists
view of thinking. Cecil's dismissal of all evidence, and
the quoting out of context, make me believe he is only
arguing. Sadly, I am beginning to believe that may be your
intention too.

There always exist a handfull of nuts. Please estimate the number of people
who seriously want CW to be outlawed. Please name a few of the individuals.

Richard Clark wrote:
"There should be two classes of Amateur radio license: Operator and Technician."

I gather the Operator would not be allowed to tinker with his radio. Only a Technician could do that.

That would be a curious prohibition because I believe that today`s regulations don`t prohibit unlicensed types from tinkering with commercial radios.

Seems about 20 years ago the FCC proposed dropping the licensed commercial operator requirement for non-broadcast operations. Telecommunications managers in all industries almost unanimously predicted chaos and worse as a result. It was a non-event, right up there with Y-2K, and in subsequent times nothing of consequence has happened. Transmitter users don`t want the hassles that non-compliance would bring, so they make sure that their radios are operated lawfully without the blessings of an endorsement from a licensed commercial operator. The FCC was right and almost everybody else was wrong.

I got my 1st phone ticket 51 years ago. Several years ago, the FCC mailed me a general ticket to replace the original. They said it would be good forever, or at least as long as I lived. I haven`t figured what it`s now good for.

Best regards, Richard Harrison, KB5WZI

> cannot be accomplished by "winging" it.

Of course, learning CW can be accomplished by "winging" it since there is no punishment for doing so. The reason that one cannot "wing" learning to fly an airplane is because one winds up dead. The only thing that happens to a poor CW operator is that the other operator pulls out or the QSO cannot be finished. It's no big deal if a QSO cannot be completed. It happens all the time because of fading MUFs.

The only CW-only bands in the entire amateur radio spectrum don't require Morse code for the license. That proves that the FCC thinks CW can be learned and accomplished by "winging" it. Why should HF have any different requirement from the CW-only bands?????

If one applied your desired rules to speech, babies would never be allowed to try to speak until they were fluent. Is that really what you want?

Hard to persuade someone who is determined "they" (those folks) are out to get him. Remember, "they" banned spark transmitters. "they" may be returning to victimize us again!

1272. Cushcraft R5 mathching network inop need help

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-16 02:55:18 UTC
From: rharrisdeja@my-deja.com
Message-ID: <940d6llme1@nnrp1.deja.com>
Source record: 172146

I just purchased an older R5 vert. and now find that the SWR is very high on all bands. I have tried a different coax and signal source and still the same result.

I assume that the matching network is bad. I have tried to get a diagram from Cushcraft...no help.

Does anyone have a diagram of the unit?

Does anyone know what the range of the matching unit is? Can I replace it with a 4:1 balun etc.

If I could find out the impedance of the trap vertical I might be able to build a new matching network.

Or....does anyone know of a replacement Cushcraft R5 matching network that I could buy for a reasonable price.

Tnx.

That's enough concrete to make a large house foundation.
In a monolith, that would be 21' X 15' X 6'.
Perhaps he meant 7 cubic yards.

> To determine the worst-case total wind load on the complete

> all the elements, booms and the mast.

That is fine if southern California is truly always and forever free of snow and ice.

To determine a worst case where ice is possible, it is better to take the largest vertical cross-section in square feet.
When a tower is coated with ice, snow, leaves, etc., it will catch a lot more wind.

Not me. I've only worked mobile at the beach so far. So have done no tests at all. But if it were me and I wanted a way to estimate if adding radials helped or not once I got there, I would would use the bandwidth as an indicator. I can think of no simpler way to test other than just doing F/S measurements. If the bandwidth shrinks any, they are helping. It it doesn't, probably not. I'm sure this won't help for pre-planning, but might be useful if you go ahead and try it. Maybe drag a F/S meter along. That would give you a second indicator. MK

Try opening the matchbox and checking things out. Look for any obvious
stuff. Clean out any spiders, re-solder contacts, and tighten all
connections. Look for cracked toroids.

Unless struck by lightning, that's about all that can go wrong. The above
steps solve this problem about 80% of the time.

Source record: 172160

The formulas are given in "Theory of Antennas of Arbitrary Size and Shape", Proc. of the I.R.E., September 1941, pp. 493-520. I think he also describes it in his book _Advanced Antenna Theory_ (Wiley, 1952). I believe I recall an analysis or comparison with measured values which shows decreasing accuracy as the antenna gets several half wavelengths long, but can't lay a hand on the reference just now. Schelkunoff's method was really super before we had so much computing power, but antenna input impedance calculations are almost always done with the method of moments or other numerical method these days. The method of moments will give very good accuracy for nearly any combination of antenna length, diameter, and shape, while Schelkunoff's method is limited in these respects. It was great work, though.

I find a lot of the people that do code well are musicians, and visa versa. There may be some aspect to music that is similar to code. Code is kinda rhythmic when it's sent cleanly and properly spaced. I can play music in my head just like a juke box. And never a wrong note ever. I can play symphonies, rock, jazz, blues, even Hank Williams, and what I "hear/play" in my head sounds the same as the record. I can play Al Dimeola, Eric Johnson, Chet Atkins, etc you name it "hard stuff to play", note for note perfect in my brain. I just wish I could always get my fingers to cooperate....They tend to balk at times. I've played music since 4th grade in school, and have played both by sheet music "drums" and by ear "geetar", but even if I didn't play anything, I still think I would have a good jukebox in my head. It's an ultra powerful instrument, "yep, I consider it an instrument to me" and far superior to anything I can play manually. But no one else can hear it...But, it's real handy as it tells me if a note is sour when I'm playing something new. So, once I work something out, there is never a sour note. I can hear a clunker a mile away no matter what scale or key. And the weird part about it is, I can think of all these scales in my head, arpeggios' whatever, and hear them in my head and eventually play them , but if you were to ask me

what scale I was playing, you'd just draw a blank. duhhhhh...I have no idea..And could care less. As far as thinking in music as far as playing geetar, you do get to the point where you can think of a note, and know what fret to hit automatically to play that note. But I think it's more from sheer practice and repetition than anything. Much like code. Also once you know all the scales etc and start playing lots of runs, it gets to the point where you can mix and match scales and runs and have them work out right pretty much on the fly. But comes after playing said runs over and over about 49322 times. There is no real shortcut to this. Once you get to this point, you can pretty much go on autopilot. Most of the good jazz and blues players play this way. They can go off on a tangent and end up on their feet 95% of the time. Stevie Ray Vaughn was real good at that playing blues. He'd play a solo slightly different each time usually. Mainly because he was on autopilot just winging it. Most the jazz players do the same. About the same way as a fast coder goes on autopilot when sending. MK

No, lets's beef it up -- require a four year degree in Electrical
Engineering. I would be all for it. It raises the bar, since getting a
four year engineering degree requires much more time and effort than
learning Morse code. Maybe there should be a four year transition period
where current license holders can continue to operate while they go back
to college. Or maybe not -- let's not baby them.

I was always a bit leary of the end fed design. BTW when my Dad passed on he left me with a 1949 ARRL antenna book. Interesting reading there, some designs we don't even see published anymore. An interesting tip too, for those of us using twin lead....coat it with silicon grease to keep rain from geetting on it and changing the impedance. Don't know if it works though.

Glenn, VK7AB wrote:
"Can someone point me towards info regarding manufacturing the skeleton slot?'

I have not seen any skeletal slot antennas. I think you need some meat on the bones to make them work.

A skeleton slot would be two quarterwave stubs short-circuited at their far ends, placed in the same plane, with their open-circuited ends facing each other and connected together. This then amounts to a narrow halfwave loop (one wavelength of wire).

The junction of the quarterwave stubs is the feedpoint.

The voltage vector is across the feedpoint as is the polarization of the radiation. A vertical slot has horizontal radiation.

Problem is, the quarterwave stubs are nearly open circuits opposite their shorted ends. The wires must be fattened (or widened) to bring down the impedance, accept power, and radiate the power.

Fattening the conductors permits phase and magnitude differences so that the fields don`t add to zero in all directions. A slot antenna has radiation characteristics similar to a dipole.

A slot antenna is made by carving a 1/2-wave long slot in a sheet or tube. It doesn`t need to be wide, an inch or two will do. Attachment of the feedlne is across the slot at its middle, so that it is 1/4-wavelength to either end of the slot. The drivepoint impedance, if the metal is extensive, is usually a pretty good match to twinlead.

Best regards, Richard Harrson, KB5WZI

When an end-fed antenna is fed with one of the transmission line wires
and the other is essentially left open-circuited, one can expect
considerable feedline radiation, unbalanced currents, and possible
RF in the shack.

What will you bet there's a big fat 50 Ohm resistor inside there?
>
> The question is how does it work?

Very very poorly. You waste about 95% of your power into the resistor.

> How CAN it work?

Simple. It's a very leaky dummy-load. The radio sees 50 Ohms on 99% of the freqs and some power leaks out the wire(s).
I made one long ago and the only time I ever used it was for working QRP since my rig had no power output control.When using the leaky-dummy people use to ask me if my antenna had blown down since I was an S2 or 3 on that stupid thing when usually I was well over 9.

>

That's pretty much it. The "skeleton slot" was invented by G2HCG sometime in the 1950s and used by his TV antenna company as a way of feeding and stacking yagis at about 5/8 wavelengths.

It's a narrow rectangular loop as Richard surmises, and the shorter top and bottom sides act as the driven elements of the two stacked yagis. The feedpoint is from center to center of the vertical sections, and is fairly high impedance. It can be fed either in the middle of a straight crossbar with a step-down balun, or with a delta match to coax.

That style of VHF antenna has fallen out of favor, but the skeleton slot has made a comeback as a multi-band 14-50MHz antenna. It behaves as three stacked dipoles (top of loop, bottom of loop, and the crossbar used to feed it) fed in phase. The system is fed by tuned open-wire to the center of the crossbar.

By not making the loop too wide, you get a simple horizontally polarized bi-directional pattern across a very broad frequency range, without the pattern breaking up at the highest frequency. The disadvantage is the height of mast required (although the mast can be metal).

There was an article by G3JYP in RadCom a few years ago, and the most recent write-up is in G3LDO's 'Backyard Antennas' book (RSGB, may be available from WIA and ARRL).

G3LDO's version is 10ft wide, 30ft high, on a 45ft rotating mast. It has three cross-booms made of tubing at 15ft intervals, and the vertical conductors are wires strung between the tubing ends. He describes it as a "14-28MHz" antenna but it will undoubtedly work on 50MHz (G3JYP used his successfully on 70MHz with the same open-wire feed).

Joe assumed 2 inches of radial ice on everything at 150mph times a safety factor. Again give or take. The whole "square
feet" calculation is bogus the way most hams use it because what really matters is a calculation of the bending moment on
the tower, not just the antenna "square feet".

I'd say that you'd be preventing the loss of about $100.00. I haven't priced coax in a long time, but I'm sure that the good stuff is much more than the $19.95/100-ft of twin-lead. I don't think the physical losses themselves are that much different at HF, but on a QRp station, I'd say make every 1/10th of a watt count. Even on 100 watts, your antenna is still the best place to put extra effort in.

With the coil having an insulated base "non grounded" the formula is
165/freq in mhz x 6.26 For a grounded coil use 305/freq in mhz x 6.26
Just guessing, I'd start with about 8-10 turns on a 1 inch form. Trim
for best match. You are tuning the antenna for a 3/4 wl resonance. MK

Jay,
Here's one way you might do it. To find the voltage on a feedline
use;
V = SQR(SWR x watts x Z of coax)
If you use 1.0:1 SWR your looking at the 'best case' voltage. If
you do the same for, say, 10:1 SWR, your looking at the 'worst case'
voltage. Crank in a 'fudge factor' of 2 x V, for instance, and you
should be safe.
A safe arching distance? Who knows, how about 1/4" per 1000 volts?
Probably something like that?
'Doc

anything halfway.

That's putting it mildly.

The installation was partially described in QST for May, 1970. The
pictures are OK, but no picture can properly describe the impression
the 107 foot tall monster made when seen for the first time. Because of
surrounding trees it was not too obvious until you were almost there.
Then it was quite obvious.

K3JH had a corner lot and a typical split-level house. The smallest
Yagi was a 3 element 40 meter job, the quad was 2 full size elements on
80 in diamond configuration. It's all gone now - the estate couldn't
find another ham to buy the place, and the big tower was cut up for
scrap.

Hi Bob...

Their only claim is supergain performance, which - to date - no one has been
able to refute empirically. Some theorists claim otherwise, of course, but
didn't they make the same claims about the Wright's flyer and Bell's microphone?

My HF rig (in the basement) picks up birdies and interference any time my TV in the living room is on. I set the rig on 14.160 and turned the volume up, then came upstairs and watched the TV. Sure enough every time the scene on the TV changed or text appeared the noise on the HF rig would change. Turn off the TV and the noise goes away. On top of all my other problems, this is not one I need. Any way to shield the rig from the noise or any filters for the TV to eliminate it? TV is only 3 years old.

Hi OM,

Hmmm, they claim supergain performance - a theoretical construct.
Theorists warn it can't happen. So, the inventors say the theorists
are wrong - for which claim? :-)

Just love these prove-a-negative issues. Let's see, speculation:
the Raibeam actually, for real, works on the infinite improbability
gain principal - anyone able to refute this empirically? :-O

Source record: 172090

It is probably radiated harmonics from the set's horizontal driver
circuitry. The giveaway is that these birdies will appear every 15.75 kHz.

If the TV is connected to a cable system or to a satellite receiver, first
try a common-mode choke on the incoming cable. Use an F-240-43 ferrite core
(Palomar) and wrap about 10 turns of the cable onto it.

If connected to an antenna, you may also need a high-pass filter on the TV
feed line.

In some cases, and additional common-mode filter may be needed on the AC
line. A differential-mode AC line filter (Industrial Communications
Engineers or Radio Shack catalog #15-1111) may also be needed.

Very rarely, it is the set's internal wiring that is radiating. If the
above cures don't work, buy a new TV.

Message-ID: <mL496.22743$OD.8423643@typhoon.snet.net>
Source record: 172092

Since I happen to have a 3000psi pressure washer, I was planning on
installing its zero-degree nozzle, and tracing the existing wires, letting
the water cut a slot in the ground. I also plan on wearing plastic all over
myself as the water will push up mud that will try to land on me !

I also had considered the same setup but attaching a small wheel to the end
of the pressure washer's wand. This wheel would have a groove in it that
would follow the wire and keep the nozzle the same distance above the ground
at all times.

Naturally this won't be tested until the spring.......

Source record: 172094

Buying a new TV without checking it for RFI may present you with new surprises. I recently bought a new RCA 36" TV and it took me a couple of months to realize that the white noise level I was seeing on 20 and 17 meters (S-7) was coming from the TV. Specifically, from the switching power supply, which has power to it all the time when the TV is plugged in. It might have taken me longer to find the problem had I not seen a letter in a recent QST where another ham reported the same problem with an RCA TV.

In my case, I was able to reduce the noise substantially on 17 meters by wrapping the AC line cord many times around one of the Radio Shack split rectangular cores. In fact, six cores were required to do the job. The big problem however, is that the power supply is completely unshielded and there appears to be no RFI suppression measures of any kind used. The final solution involved installing a remotely controlled on/off switch in the TVs AC line. An MFJ-1026 Noise cancellation unit is used to kill the noise when the XYL wants to watch the TV while I'm on the air.

Anyone looking for a new TV really needs to perform an RFI test on the store floor before buying. I took my little Sangean SW portable receiver to the store, tuned it to 17 meters, and checked out various TVs by placing the receiver up against the case near the rear of the set. The RCA's were the absolute worst at producing the white noise. The Toshiba 36 inch TV was substantially quieter, but still produced a very strong white noise signal.

Note that conducting this test requires a VERY cooperative store staff, since you want to power off all but the TV being tested. If you don't do that, you'll hear nothing but white noise and birdies everywhere in the store.

Hi Richard,

Apples and oranges... If proper empirical measurements were made, the *negative* could be either proven or dispelled. In this case, the problem as I see it is a belief in the infallibility of mathematical solutions... the empirical world be dammed!

When one holds science in the same light as religion, little progress can be made - as it is more a matter of knowing, not believing. For example, you can study to learn Ohms Law and believe that you *know* all about it, but only after you *prove* it empirically with a power source and a handful of resistors will you truly have the knowledge. JMHO :-)

> these tests will be published.

Have the results been published yet? I think all of us would be
interested in taking a look at your "emperical" evidence. And how big
did the "S units" end up being in dB?

Why not sign your real name to your postings?

Nope. Not even close. Passing a code test is much easier than passing
the technical tests anyway. So, even without a code test, TANSTAAFL.
Or game, as the case may be. Of course, if it's so easy, why oppose
it? The tea tax on the American Colonists was a pittance, why did they
oppose it?

Maybe I should have said:
It's like requiring paid ticket holders to the game to take a pitching
test before they can get inside the stadium, but allowing them to get
close enough to listen with just a paid ticket.

The technical test is the real pay for the ticket anyway, not the
archaic code test.

All men are created equal; they work to become unequal.

Right you are, Bill. The ham-vendor passed that along as a suggestion,
and it seemed worth passing on since he states he has some customers who
report that it is working for them. Without time for a lot of discussion
of it, I came away with the idea that he was referring to it as though
using a 1/4 wave element and an unspecific ground plane, in the vertical
plane rather than as a horizontal dipole. I haven't tried any of this
yet but probably will. I always used a tuner of some kind on a loaded
antenna for access to more of the band anyway since they're naturlly
narrowbanded.
He was referring to the coax shield side as the "cold" side, Not that
it matters. As a dipole it is still supposed to be a balanced antenna.

Hi OM,

What you are responding to is the
>belief in the infallibility of
fill-in-the-blank which also includes empirical measurement. (I
beleive you may have already said that above.)

Having sat at the standards bench making empirical measurements for a
number of years, I have been able to confirm many theoretical
subjects. That's Apples. I have also observed others claim they
could perform empirical measurements to disprove the same theoretical
subjects - Oranges. Having been trained in the science of
measurement, Metrology, I think that I have at least the humility to
know that I only got close, and never as completely right as the
critics believe themselves to be.

Those folks have the heart of the righteous, the belief of the
converted and yet are no closer to truth than before they went on
their quest. What is worse, their convictions cloud their objectivity
with proclamations of Theory - bah humbuggery! My response to your
posting reveals that such acolytes use authority to deny and refute
the same authority.

Empirical measurement is the heart and soul of engineering, and the
basis of scientific progress. It often preceeds any law pronounced
from on high. Georg Simon Ohm noted resistance far in advance of his

Law, and yet the scientific proof of his law is a circular argument because the Ohm is defined by an Empirical measurement of a Physical (not Theoretical) Standard.

I am sure there are many here who can measure an Ohm, or is it 1.1 Ohm, or is it 1.01 Ohm, or is it 1.001 Ohm or is it... ? I have done this empirically to 7 places, absolutely accurate to 6. But what does it prove? Only that the resistor I measured conforms by empirical measure to a standard that is an empirical measure. The theory accounts for many variables in the empirical measurement and brings that measurement to higher accuracy. To dismiss the theoretical and accept any measurement is a contradiction on the face of it.

This, of course, is my not so mumbled opinion.

And when I assert, based on 8 years as a practicing VE, that the current version of amateur radio license testing tests for nothing but the determination of the examinee to get the license, and that no learning whatever is required,
I am slammed by several learned persons who basically despise my attitude toward Morse code. They insist that hams should have NO particular technical qualifications, rather they will all be certain to learn whatever they need after the license arrives! I assert that many ham applicants come away from the testing process with Extra class licenses yet can't work an Ohms law problem nor figure the demensions of a halfwave dipole, and I am castigated for even mentioning any such thing.
Methinks there exists an Agenda with perhaps twin purposes. Get rid of Morse code in ham radio and get rid of technical content in the tests. What will become of the ARS following all that is problematic. For sure it won'tbe recognizable.

Dunno - the end-fed zepp is a big brother of the "J-pole" antenna popular on VHF. I've not seen that produce RF in the shack etc. on VHF. Of course, the J requires specific dimensions and configuration. If you just use any old length of wire and any old length of transmission line, you do tend to get the unpleasant effects that Cecil describes...

The above unit is a remote controlled coaxial rf switch that may be tower or mast mounted. It only requires one feedline to operate up to four(4) feedlines. This is for HF freq only, not 2 meter.
The Ham I bought this from used it for two weeks. It did not cover the 2 meter band. He bought the RCS-8 which does.I have never used the unit. It is still in the original box, instructions. etc
$60.00 shipped conus/funds to be in a money order.

Hi Roy,

FYI; Originally I was under the impression that the tests being conducted in Canada was being done by the RAC. This has since been clarified and these tests are being conducted by RAC member VA3KA independently of the RAC. Nevertheless, the results of these tests will be included in an article, but I have no further knowledge regarding the particulars. In the VA3KA tests, the Raibeam RB-36x continues to outperform the Cushcraft A4s by a respectable margin on all bands... FWIW.

I suggest however, that you don't miss the review of the Raibeam RB-24w by Paul Carr, N4PC in the upcoming February issue of CQ Magazine. Perhaps you can then focus on deriding other people's findings and get off of my back :-(

Close, but no cigar. The only test needed is for knowledge of how to operate and obey the rules and regulations.

Fine the violators.

No need to get rid of Morse, RTTY, ATV, or any other compatible mode. No need to test for proficiency in any mode. Nobody gets seriously hurt by unskilled operations on the ham bands.

No need to test for understanding how radio works anymore than testing applicants for drivers licenses on how cars work mechanically. All applicants for either license should be tested on is how to operate and how to obey the law.

The distinguishing characteristics of amateur radio are, it is non-commercial, and it has no prescribed channel assignments.

Best regards, Rchard Harrison, KB5WZI

It's well established that those who want code testing to end globally
will give no quarter in their quest. They will allow no attractive or
useful attribute to accrue to the mode for any reason whatever,however
accurate, true or how well justified.
I think you've reached the obvious and only logical conclusion.

The VEC fee is a session fee which means you can take as many exams as you like at a single examination session for one $10 fee. If a VE is charging the $10 fee per element at the same exam session, he needs to re-read his VE manual.

Dick, the fact that no dictionary or encyclopedia lists Morse code
as a language does not detract one iota from its usefulness as a
coding method for English or any other language associated with
RF communications. CW is attractive to some hams and possesses
some useful attributes like S/N superiority over SSB, near minimum
hardware, etc.

Jay wrote:
"Looking for a reference book or web site that explains what is required for an insulator---."

OK, The American Institute of Electrical Engineers, a predecessor of the IEEE published a list of spark-gap voltages eons ago. These break-down voltages depend on temperature, pressure, the electrode shapes, etc, to some extent. A summary of the AIEE information appears in the CRC "Handbook of Chemistry and Physics".

Between needle points the spark will jump about three times as far as it will between good sized balls.

When considering a-c voltages, the peak voltage is available during the cycle to initiate a spark. Once initiated, the cloud of ionozation is persistent and the arc can persist through the a-c alternations. The value of the peak voltage is 1.414 times the rms (effective value) of the applied voltage. RF is a-c of high frequency.

On transmission lines, SWR is a ratio of maximum and minimum voltages or currents found on a line. Fortunately this is not a multiplier of the rms applied to the line. The maximum voltage will be a maximumm of 2 times the peak voltage found on a line with no reflections. That is because the doubling is the sum of the peaks of the forward and reflected waves. The reflection can`t exceed the vigor of the forward wave which produced the reflection. Only when the peaks of the forward and reflected waves are equal and in-phase will the double-voltage peak occur. A complete open or a complete short of the line is needed to produce a complete reflection.

Here are a few values from the AIEE values of peak kilovolts between needle points and the gap a spark can jump under standard atmospheric conditions.

5kv:0.42cm, 10kv:0.85cm, 15kv:1.30cm, 20kv:1.75cm, 25kv:2.20cm, 30kv:2.69cm

Well, the table goes on and on, but we are already past a gap of one inch, and you can look up the rest in the CRC handbook.

Best regards, Richard Harrison, KB5WZI

1346. Interference in my shack *** update ***

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-17 05:02:28 UTC
From: VE3TMT <mdonoghue1@sympatico.ca>
Message-ID: <EH996.81602$n%.3260915@news20.bellglobal.com>
Source record: 172020

I decided to unplug everything in the upstairs area of the house. This meant the computer and associated junk, the tv's the satellite rcvr, vcr's, playstation..everything. Went downstairs and turned the HF set on and voila the interference was gone. So just to test, I dialed up 1.910 (previously S9 + 20 noise level) and it was quiet as can be. I turned up the audio and came back upstairs and turned the computer on. The noise was back. I could actually hear the hard drives spinning up in the 450! After the computer finished rebooting I turned it back off and went downstairs. Tuning up from 160m the noise was nowhere to be found. Remember at this point the offending TV is still unplugged. Now there was a constant buzz around 9.5 Mhz up through 20m. I came back upstairs and began unplugging the computer parts again until it went away. I was caused by one of those Playstation devices called DexDrive that allows you to load games off the net. I unplugged it and checked the bands...all quiet again. I have always left my computer on 24/7 so never thought it to be a problem. So what I have determined is I have two main sources of RFI getting into the rig. The living room TV and the computer which is on the other side of the living room 1 floor above the rig. I guess my first step would be to wind all offending cords with chokes, or perhaps AC line filters, as has been suggested.

There is still a bit of power line noise on 40m, but nothing to worry about, that is being investigated by the power company. For the first time I actually have no noise level showing on 160! Sorry for the long explanation, but I figure if I explain it as best as I can, I'm not leaving any information out. And besides, it helps with my typing speed!

I appreciate all your help.

73,
Max

>

I don't doubt for a moment that there is a measurable effect, that's
why I used the words "no discernable effect". For I have carefully
checked factors like beamwidth and front to back, side,sidelobes and
rear rejection of the beam while using a steel mast, and if there's any
effect on the performance of my 11 element Cushcraft I can't tell it in
operation. I can assure you and everyone else, I'll never give up the
benefits of using a steel mast to gain whatever small amount of
advantage a nonconductive type mast might offer.
I suppose it may be another case of successfully "doing it" for years
and years before learning that it won't work.

Morse isn't outdated, either.

But neither knowledge of Morse nor electronics is absolutely necessary to operate some ham stations. Otherwise qualified people are being kept off the ham bands by the written tests.

You might consider that when you and others insist that there is
nothing more than "novelty" benefit to the mode that is the functional
equivalent of saying that is it useless and therefore not worth
preserving. When the clamor by those who would expand the voice segments
to the maximum limit consider your statements, how then will you react?
And what good could it possibly do?

And you clearly overlook the fact that some posters here clearly state
that Morse code is long past usefulness and the implication is clear
that as far as they are concerned, it may as well pass from the scene.
In fact, your rantings frequently convey that impression.

It is extremely revealing that you see NO difference between a spark transmitter and radiotelegraphy using continuous waves.

If that is permissable evidently they have changed the rules. When I
ran a VE team ('85 thru '93) the rules said one fee for all tests taken
at that session. Later it was deemed permissable to charge an additional
fee for a retest of a failed element at the same session, but we never
did.

Beg to differ. As a Public Safety communicator I have experienced
interference from hams that could easily have caused serious problems.

>
> No need to test for understanding how radio works anymore than testing
> applicants for drivers licenses on how cars work mechanically.

While doing that same job- Public Safety communicator- a part of my
duty was to receive preliminary accident reports including a statement
of facts. I saw all sorts of evidence that much more training on "how
cars work mechanically" would have been beneficial, especially WRT how
the laws of physics control them in braking, skidding, centrifugal
forces, etc.

All
> applicants for either license should be tested on is how to operate and
> how to obey the law.

You have a right to your opinion, erroneous as it is. I suppose that
you would recommend a consulting engineer to do their ALL technical
work, instead of just a part of it. After all, why should any "hobbyist"
need to know how to construct a simple dipole or anything else so
mundane?

> The distinguishing characteristics of amateur radio are, it is
> non-commercial, and it has no prescribed channel assignments.
>

You've just managed to describe CB and the Family Radio Service. To say
nothing about the Freebanders - I saw nothing in your post that said
"ham radio license".

Unless the ARRL has changed, it's not quite a session fee. It is insofar
as you can take one of every element for one fee. Retakes of failed
elements are subject to another fee.

Hello,

I recently came by an Yaesu G-1000SDX rotator at an very affordable
price, I was however warned the the rotator's control cable plug was
missing. Upon checking with our national Yaesu distributor I was told
that this was an propritary plug and they would like to charge about
80 USD for it. This is the round 6 ping plug which goes into the
rotator, not the rectangular entering the control unit.
Does anyone know if there exist an replacement for this plug?

I turned up the audio and came back upstairs and turned the computer on. The noise was back. I could actually hear the hard drives spinning up in the 450! After the computer finished rebooting I turned it back off and went downstairs. Tuning up from 160m the noise was nowhere to be found. Remember at this point the offending TV is still unplugged. Now there was a constant buzz around 9.5 Mhz up through 20m. I came back upstairs and began unplugging the computer parts again until it went away. I was caused by one of those Playstation devices called DexDrive that allows you to load games off the net. I unplugged it and checked the bands...all quiet again. I have always left my computer on 24/7 so never thought it to be a problem. So what I have determined is I have two main sources of RFI getting into the rig. The living room TV and the computer which is on the other side of the living room 1 floor above the rig. I guess my first step would be to wind all offending cords with chokes, or perhaps AC line filters, as has been suggested.

There is still a bit of power line noise on 40m, but nothing to worry about, that is being investigated by the power company. For the first time I actually have no noise level showing on 160! Sorry for the long explanation, but I figure if I explain it as best as I can, I'm not leaving any information out. And besides, it helps with my typing speed!

I appreciate all your help.

73,
Max

The latter is a subset of the former. Your satisfaction is not my concern.

You won't "hear" me "say" anything on Usenet. It's a text-based mode.

Then you agree that your earlier statements about nobody wanting to eliminate
Morse were incorrect. "Nobody" means "not one person". Thanks for admitting
your mistake, Cecil.

The existence of counterexamples disproves a statement like "There is no
crusade against the mode."

> Please estimate the number of people who seriously want CW to be outlawed.

I'm not sure. There are/were several of them regularly posting to another
newsgroup that I don't bother with anymore.

I'm going to assume that CQ magazine is not "peer reviewed", at least not in
advance of publication. I'm sure, however, that the article will be reviewed in
this forum after the fact. Pity if a lot of bogus claims and conclusions are
foisted off on the uncritical readership of CQ before that happens.

If those claims are based upon, as it was suggested earlier, mounting different
antennas in different locations and "comparing" them in "S-unit" differences
then the discussion is going to be a catfight.

So much for FCC device approvals . . . Both the GE and RCA brands of consumer electronics lines are actually produced by Thomson. I've had nothing but grief with their stuff starting with a GE feature phone & answering machine which was a complete crapper then a tabletop AM/FM clock radio which was just as bad. I wouldn't touch a "GE" or "RCA" anything with a ten foot pole. When it comes to TV rcvrs I stick to Hitachi, Sony & Mitsubishi, ya get what ya pay for.

Last year, I changed that statement to, "Hardly anyone wants to eliminate
Morse code. Let me rephrase: Nobody who matters wants to eliminate Morse
code. A lot of people who matter want to eliminate the Morse code *requirement*.

> Here's a hint: The organization isn't called "No Code TEST International".

Now Jim, you know that TLAs are much superior to FLAs. Please read the
NCI charter. It specifically states that they want to remove the code
requirement, not the code. Do you have any valid evidence that the
NCI BOD doesn't intend to abide by their own charter?

if I put outdoor TV antenna in the attic ?

Detailed story:
After my last post I bought an RCA 3036x (110 in. boom and 36 elements)
as suggested. I would like to put it in the attic. But I do not know if I
need to
ground the antenna in case of lightening.

Thanks !

Rus

Last post:
==========
Hi,

I live in the flat area about 50-60 mile from new york city.
I would like to buy a outdoor TV antenna to boot the TV
signal broadcasted from NYC..

I have several questions as follows:

1. what is the difference between
the antennas where the UHF element
are either vertical to the axis or V-shaped ?

top view:

```
| | | | / / / /
---------- or ----------
I | | | \ \ \ \
```

2. how many elenmet is appropriate ?
3. how long the boom is appropriate ?

Thanks !

Rus

Dick Carroll wrote:
"You`ve just managed to describe CB and the Family Radio Service. To say nothing about Freebanders - I saw nothing in your post that said "ham radio license"."

Dick quoted me: "All applicants for either license should be tested on is how to operate and how to obey the law. And my quote: "The distinguishing characteristics of amateur radio are, it is non-commercial, and has no prescribed channel assignments."

Hello! Amateur radio = ham radio.
Hello! Licensed is not unlicensed.
Hello! Channels 1 through 40 are not the same as 28,000 through 29,700 kHz.

The Pizza Hut could legally take your order and dispatch it using CB radio, but could legallynot use amateur radio to do the same. This is simply the difference between commercial and non-commercial.

Dick Carroll obviously chooses not to understand what he reads.

Source record: 172054

Hi,

I am thinking of putting up either a 40 meter or 80 meter skywire antenna. I understand that a skywire (which is just a horizontal loop) can be a VERY effective DX antenna especially if you have it up high enough!

I have room for both. Which is a better antenna a skywire cut for 40 meters or a skywire cut for 80 meters??

I assume that the 80 meter skywire may not perform as well on 10 meters etc.

I also understand that you can use the feedline to the skywire as a VERTICAL with the loop being a top hat!! So I could use a 80 meter skywire as a vertical on 160 meters!

How should I feed the skywire?? Should I use coax or ladder line??

I would like the use the antenna on SSTV and RTTY using a kilowatt. I am afraid that the coax might melt due to high SWR on the feedline.

If I use ladder line, can I use the ladder line as the VERTICAL element with the sky wire being the top hat?? Or is coax a better feedline when using the skywire as a Vertical / Top Hat??

Any ideas?

The ARRL VE book, said, 1 fee for each test session, and it covered as many elements as the test taker wanted to take, or the VE have. But it is a new fee to retake a failed element. So as long as you keep passing you can do as many elements as you can pass for 1 fee. Remember though that most VE sessions have only 2 or 3 versions of a test element available and if you flunk all that they have, your done for that session.

Dick Carroll wrote:
"It is extremely revealing that you see NO difference between a spark transmitter and radiotelegraphy using continuous waves."

Incorrectly reading between the lines, Dick Carroll again makes a false accusation.

Electronic "smoke signals" can be transmitted to convey information. A variety of display sources can be used. Spark or CW transmitters can be switched on and off. A light source can be flashed in code. A.G. Bell used a mirror to flash coded and modulated signals using the sun as his light source. This technique isn`t limited to on-off coding, a variant of this, the light valve, has been used to record sound on film since the inception of the talking motion picture. Edison probably initiated the light valve as another use for his incandescent lamp.

Morse code was designed to convey information by interrupting an electric current. Any interruptable medium can be coded. RF can be interrupted almost as easily as d-c. It makes no difference if the source is a spark transmitter or a CW transmitter when it comes to coding.

Spark transmitters were banned because they polluted the radio spectrum. Smoke signals are banned in many jurisdictions because smoke is an atmospheric polluter.

Once A.G. Bell invented a transducer between sound waves and an electric current, on-off signaling was mostly superseded. Bell`s patent has proved to be the most valuable ever issued.

Obsolescence is the commonest occurrence in technical experience. You write with a ball point pen. Quills and ink wells have few users today.

Antiques are highly prized by many. More power to those who would protect and preserve that heritage. Just don`t impose that junk on me.

Best regards, Richard Harrison, KB5WZi

Keith,
the size of the wire isn't important. As long as it's strong
enough
to hold it's own weight, it's big enough. What that means is that if
it's bigger than a #24(?), it ought to work fine. I would use
insulated
wire. It certainly won't hurt (and may help) if you use more than one
counterpoise.

It's been a few years, but when I made General, I took the Tech,
General, and 13 WPM code at the same time for one fee ($6.45).
At another session I took the Extra and the 20 WPM code tests
again for one fee ($6.45). At the time, I was under the impression
that this fee went directly to the ARRL, to cover the cost
of the testing materials that they supplied. That ment that the
club, which was running the VE session, was really charging
nothing for their time.

Was I correct in my reasoning? Aren't they, the club, also allowed
to charge a small fee to cover their expenses?

It doesn't matter since you short both feedline conductors together
at the ground level feedpoint. You need a good ground plane just
like any other ground-mounted vertical.

Hi Richard,

There are far more distinguishing elements - many are cumbersome deferences to commercial interests. Commercial interests are a very defensive bunch (moreso than ourselves).

I cannot transmit entertainment. In essence there is no non-commercial entertainment radio operations permitted by our class of licenses - not simply non-commercial operation.

The "Rules and Regs" are tested to this point for the dry and soul-killing reason of a commercial interest mandate. No one will come to harm if I did - except by the perception of commercial interests. We need look no further than LPFM and the commercial lobby trying to strangle it in the crib.

We broadcast now. Every sunday morning here in the Pacific NW we have a Ham swap, my buddy's repeaters carry the HF coverage. And yet this provision of no entertainment was balanced on the notion that we could not "broadcast." That distinction is clouded and there are other examples.

I would love to operate an amateur radar station to do Ionospheric testing - this too is not allowed. What harm does it bring? Speculations may abound, but certainly it falls under that now foggy precept of broadcast (a transmission without an intention of conversation).

As for the claim of not being channelized, that is simply a faint observation of a slim technicality. If the Ham bands don't qualify in this regard, it is only because of the strict reading of the statement, not the practical rendering of it in operations. Given SW broadcasters can shift their frequencies as their marketing officer dictates, the notion of channelization is simply which frequency do you sit on today, this month or last year. Channelization is for market stability, not spectrum accomodation. (This does not go to other commercial operations such as dispatching, but then they are confined to UHF/VHF where we as Hams have what appear to be ...

channels!)

Hi Dick,

First, a commendation for your tenure as a VE.

As you may note by my two tiered approach, I find nothing wrong with novices (not the license categorization) finding their way into the hobby by fumbling through the technology - that is the single greatest opportunity offered us and why we are called amateurs. I would let anyone in as an Operator who can offer proof of breathing. Technician? No ******* way! Even some pro's wouldn't qualify (especially those who hold doctorates - their bozo certificates - to my face).

Richard Harrison has taken me to task for this two tiered approach (I too held FCC 1st now GeneralRadioTelephone) where there is no apparent mandate on the commercial side for distinctions of Operator and Technician. But that is why they (and he) are professionals. My suggestions in that regard are perhaps not met with universal appeal (are anyone's?), but the sense of what I am trying to impart is that Ham radio needs more people and those people need the immediate gratification of actually talking to someone, somewhere else, by the effort of their persistence (rather than dialing a number or logging on) to appreciate that perhaps they could do better if the knew more. They need to feel the spirit of the call, rather than the hammer of the code.

On the other hand, there are those who have much less interest in that thrill of the call, and are more interested in its quality, or how it could possibly happen in the first place. For these folk, the spark of interest resides within the intellect or the skill of hands on. This is not to say they are cold and indifferent intellectuals, neither does it suggest a criteria for entry into these ranks. Technicians have as much opportunity for the chase as Operators.

The two distinctions of Operator/Technician are not self negating, they aid one another. Those Operators, when their interest rises above the static, will want authoritative answers. If they are not satisfied with what they perceive to be bogus answers, they have every opportunity to challenge them by study and move into those ranks of recognized authority.

The current tack is the promise of some future reward if the current Novices/Techs can perform the stages of the cross now. This is entirely unacceptable for the future of Ham radio.

Almost anything is effective to dx if it's high enough. I don't know if
I would call it VERY. Compare to a good beam on 20-10m, and the VERY of
the loop will refer to as in VERY MEDIOCRE. But saying that , it'll
work. But so would a dipole at the same height.
>
> I have room for both. Which is a better antenna a skywire cut for 40 meters
> or a skywire cut for 80 meters??

Dunno, depends what band it's used on. I would download the eznec demo
and run it though the mill on all bands used. That should give you a
decent idea. If you plan on using 80m, of course the 80 loop will be
better.
>
> I assume that the 80 meter skywire may not perform as well on 10 meters etc.

Maybe not. eznec might give a you good idea about that. It might be
better or worse...

Yep.

Ladder line if all band use.
>
> I would like the use the antenna on SSTV and RTTY using a kilowatt. I am
> afraid that the coax might melt due to high SWR on the feedline.

You sure you need that much juice on sstv/rtty? Good gravy, you will be
browning the food in the area.
Your tuner used will be the critical part if you use ladder line. You
will need a BIG STOUT tuner. And ladder line with thick gauge wire. Like
#14 or so. Don't get the thin wimpy stuff. I used to run SSTV on 20m a
bit. But I found 300-400 watts video usually plenty. My henry wouldn't
even hardly blush the tubes at that level. A full KW of sstv is going to

hard on everything involved. Rig, amp, the whole bit. For an example, on my 100w icom I ran on sstv at that time, I didn't feel comfortable running more than about 30-40 watts sstv. I go by the rated AM duty cycle just to be on the safe side. Running a full 100w sstv from a rig for minutes on end will get things a cooking good unless you have some good blowers going.

> If I use ladder line, can I use the ladder line as the VERTICAL element with

You can try different routes. Some might work better than others. You can short the ladder line together and feed as a random wire. You could also have a jumper to disconnect the opposite side of the loop from the feedpoint. Unhook the jumper and convert the 80 loop into a 160 diamond shaped dipole. It might work ok. Most of the people I know that run these type deals just experiment until they find what "works" the best on 160. You can usually feed two or three different ways. PS. you can make a remote "switch" from coax to short the far end of the loop. Lets you change to dipole mode from the shack. Or at least I hear it will work.. I haven't tried it. MK

Oh yes, I agree with you that almost any antenna will work pretty good for DX if it is high enough.

But I am not a big fan of dipoles. (It has nulls at the end and is NOT omni directional enough for me). I like verticals (which I use successfully for DX on 10 to 40 meters).

But I do not have an antenna for 80 or 160. I am looking at a skywire since it is my understanding that a skywire is more omni-directional than a dipole and is likely more effective!

The ARRL VEC allows the VEs to retain a portion of the fee (up to $4 of
the current $10 fee, which is per session, not per exam) to cover
expenses if they wish to do so (this wasn't originally the case). The

ARRL requires that records of such expenses be kept, although the FCC no longer requires reporting. The FCC also no longer specifies the maximum amount which can be charged (there never has been a minimum). ARRL/VEC is charging $10, but others may charge more or less; the marketplace will probably decide.

From the ARRL letter, December 15, 2000:
==>FCC OPENS DOOR TO INCREASED TEST FEES FOR 2001

The FCC has suspended its regulatory limit on the reimbursement fee for Amateur Radio examinations, and the ARRL VEC says a new $10 test fee will go into effect January 1. An FCC Public Notice released December 4 explained that the Commission did not plan to announce a maximum reimbursement fee for 2001 since the requirement to do so no longer appears in the Communications Act.

For now, the FCC says, it will suspend enforcement of the fee provision, ?97.527(b), which continues to appear in the FCC rules. Some, if not all, of the nation's other Volunteer Examiner Coordinators are expected to follow suit, although at least one VEC charges no test fee whatsoever.

ARRL VEC Manager Bart Jahnke, W9JJ, says the ARRL VEC's current fee of $6.65 was based on the provision in the Communications Act, adopted in 1984, that established a $4 cap on reimbursement of out-of-pocket costs with an annual adjustment based on the Consumer Price Index. The new, higher fee reflects the fact that the ARRL VEC is doing more of the work on behalf of the FCC than was originally envisioned when the provision was included in the Communications Act. That effort includes data entry for all new and upgrade license applications once done by FCC staffers.

ARRL VEC volunteer examiners will continue to charge applicants $6.65 through the end of 2000.

Hello,

What is an effective scanner antenna that can mount on the eave of house? A vertical or the spider type I see advertised? I live out in the country but on top of a hill. O web location for best service and pricing would be great as well

Thanks

Roger

Agreed. A little knowledge is a dangerous thing. It sharpens the appetite for more knowledge. I took the tumble through the EE degree too. But, I surely don`t think technical knowledge beyond a bare minimum should be required of radio amateurs.

But they would have to be really high in terms of wavelength to really see those nulls on the low bands. At least a halfwave up. Which would be appx 250, and 120 ft up for each band. In the real world you do not really notice the nulls to any great extent when the antenna is low. So either is really omnidirectional enough unless super high. If you want a real good omnidirectional pattern with a horizonally polarized antenna, use a turnstile. "crossed dipoles" fed with a 90 degree phase line between the two. But these antennas are all best for regional use on the low bands. If you want to work dx, you would be better off with a vertical on the low bands also. A one w/l loop on 80m will not really be any better than a dipole at the same usually avg low 30-60 ft height, so to me it's just extra work needed to install the loop. I've tried them both here on 80m and couldn't really notice much difference in overall performance. For general coverage work on 80m I think the turnstile hard to beat. It's always been noticable when I've switched from a dipole to a turnstile. And the increase is in all directions. Doesn't really make sense on paper, but they work well. MK

Hi Richard,

You are correct about obsolescence - I haven't used a ballpoint in 30 years. However the pen in my pocket is a fountain pen (Mont Blanc). OK! OK! It's mostly for looks (the Mont Blanc is actually inferior to my Cross fountain pen).

When I have to scribble something (often), I generally reach for a Pilot (but that technology, a porous ceramic tip, has been around for a long time too). When I want to "write" something (rarely), I use a fountain pen. Either way it comes out in drafting/engineering block print - heaven help those who have to drag their eyes across my cursive (another obsolete mode? after all, it isn't "required" anywhere beyond the 6th grade).

There I go again, upsetting the demographics. :-)

And it isn't I don't think. The tests are pretty minimum now for a tech that can run up to 1500w output on vhf/uhf. I question the abilty of many of the no-code techs I've heard on the air to properly deal with that kind of power on vhf/uhf. You see very little if anything on the tests about it. They are pretty much left to their own devices in that dept. I think the combo of a new technician ticket and a legal limit tube amp for high frequencies is a fairly risky proposition unless they have experience dealing with them in a previous life. Luckily most seem to not need that much horsepower for the repeaters...I'm sure not all new techs are dummies, but frankly I was surprised they gave an entry level ticket holder full power on those bands with no real test questions in that area. I've seen a few have trouble hooking up a mirage brick, much less dealing with a 2 meter henry floor console. I'm surprised more haven't fried themselves than we've heard of lately. :/

I would ground the mast holding the antenna to a water pipe that runs
though the attic if there are any. If there aren't any, I probably
wouldn't worry about it. It's possible for it to attract a strike, but
the chances are fairly low. If your house is out in the open with no
trees or anything around, I would worry more than if the house had trees
and other objects around it. If you are really nervous, put a lightning
rod on the house. That will lower the chances of a strike to the antenna
to nearly zip. MK

Hello
My name it&#65533;s lucio and my work is in a ship repair, electronic and other.
The automatic antenna tuner AT-120 work very fine, not problem with operation in mobile marine station, the current antenna in marine it&#65533;s a simple vertical wire or antenna with 7.5 meters and the ground it&#65533;s a connection to the sea, all amateur ship with navigation to the sea work in this conditions, in this moment they are a regatta Cadiz (sud of Spain) to La Habana (Cuba), (http://www.cadizlahabana.com), the first day had a 3/01/2001 and the finish aproximately 29/01/2001 in Marina of Heminway (Cuba), all ship&#65533;s working with a Furuno or Icom BLU, with automatic antenna tuner but the better it&#65533;s a Icom AT-130E.
With G5RV, sorry they have not experiency.
But in marine conditions it&#65533;s the currently solutions,

I was referring to the recent post where you said there was no crusade and nobody wanted to cut out anyone's fun with CW. Or words to that effect. You made a mistake, that's all.

> Let me rephrase: Nobody who matters wants to eliminate Morse
> code.

So you deny the rights of those who want to eliminate it. How would you feel if someone said "Nobody who matters wants to eliminate the Morse code test"?

>A lot of people who matter want to eliminate the Morse code
requirement.

I see. Their opinion determines whether they "matter" or not. Uh huh.

> > Here's a hint: The organization isn't called "No Code TEST
International".
>
> Now Jim, you know that TLAs are much superior to FLAs.

I don't know what you mean by TLAs or FLAs. Please explain.

>Please read the NCI charter.

I have. If they mean what they say, why the name?

> It specifically states that they want to remove the code
> *requirement*, not the code.

And I think, and have said, that most of their members want that and nothing more.

> Do you have any valid evidence that the
> NCI BOD doesn't intend to abide by their own charter?

I'm talking about certain individuals. Read their posts - the evidence is right there. When somebody wants to do away with all subbands by mode, and allow HF DSSS with no consideration of its effect on narrowband users, that cuts into my CW fun. And others' SSB fun, etc.

Even when the impact of such proposed operation is pointed out, the person I'm thinking of still thinks it's a good idea. "Let there be a free market of modes" was one buzzphrase. And if it raises everybody's noise floor for miles around, too bad.

Is that a good ham attitude to have towards other modes?

High Sierra & Don Johnston's DK3
There are various others making screwdrivers but they all seem to be
knock off copies of the DK3, Why buy a copy when you can have the
original for less.

High Sierra Is more expensive but would appear to be more complete
(I.e mount is properly sorted out for cars etc.) Since your friend
will need to make his own mount anyway to mount on his van (I mounted
my DK3 on the front bumper) he may be better off with the DK3

The DK3 is better than the High Sierra in several ways

1/ it has A Zmatch built into the antenna (No need for matching
xformer)
2/ it has a very nice Quick release system.
3/ it is cheaper ($150 from www.hamradiotoys.com)
4/ It's nicely made (as is the High Sierra) and Don is the original
patent holder for this type of antenna.

With the DK3 you will have to build your own mounting arrangements and
you will have to do your own weather proofing, but this actually
allows for more flexibilty in a van install.

Vans make GREAT mobile stations as there is a decent ground plane for
the antenna to work against. Just get all the System (antenna, RIG
etc) grounding properly sorted and the antenna base matching
arangements optimized and you will be a booming mobile Signal on any
HF band.

if you want more info and some pictures of how I installed my DK3 on
my VAN (My VAN is a Long wheel base Volkswagen T4 transporter) just
drop me an e-mail.

At one time that was completely correct. I ran a DeVry/Great Lakes core from 1984 (before League involvement, by the way) through 1993. At first the local core didn't get anything, but eventually DeVry/Great Lakes started a core reimbursement progam. By the time they folded and we changed over to ARRL, the League was reimbursing up to $4 to the local core.

> That ment that the club, which was running the VE session, was
> really charging nothing for their time.

Also correct. That's why we are called "volunteer examiners." My club, however, covered all my costs for materials since I prepared all of our written and code exam materials and purchased or prepared other materials such as blank paper, pencils, 610s, etc.

> Was I correct in my reasoning? Aren't they, the club, also allowed
> to charge a small fee to cover their expenses?

Not at the VE Core level. Only at the VEC (coordinator) level. And when a VEC does allow expenses to be covered by a core, it's always as a rebate from the VEC (I speak from DeVry/Great Lakes and ARRL experience only).

I'm sorry you had that experience. I can't answer whether a VEC can instruct their cores to charge for each element. I can say that ARRL does not, nor did DeVry/Great Lakes when I was with them.

Who was the VEC for your exam? I have my own suspicion, and if I'm correct it's further confirmation of why I will never have anything to do with him.

Irrespective of who it is, it's an example of poor training of the VE team. That's one of the things that should have been basic in their instruction. I suggest you write a letter of complaint to the VEC.

I've often done this, especially in hotel rooms in metal-framed buildings which killed the signal inside (I hooked up the wire near the window). It's often the only way of receiving the good old BBC (and REAL news) in benighted places (eg like the USA!). However, a long 'clip-on' wire might cause overloading of the receiver (possibly on frequencies well away from from where you are tuning). It may be better to put the wire where it has the best chance of picking up a signal (near a window, as I said) but give the radio only a 'sniff' of the signal. Ideally, you would place a variable capacitor at the junction of the wire and the telescopic antenna (in series), and use it to adjust the amount of signal fed to the receiver. However, if you don't have such a capacitor about your person, you might try simply winding the wire (I'm assuming that it is insulated, so that there is no direct connection) MANY times around the telescopic antenna. Adjust the number of turns, as necessary, if you have to. It's a bit cheap and cheerful, but it does work.

A more 'sophisticated' method would be to use a proper antenna tuner (you would probably have to make it yourself - not complicated, but not quite the same as tuners used to feed radios with a proper 'antenna input' socket. You would connect the ground side of the tuner to the 'chassis' side of the circuit (yes, I know there is no chassis - try the ground side of the battery clip - if it has batteries). The tuner design would have to give a high impedance feed to couple to the antenna. This actually might work pretty well!

Ian.

I guess it's a matter of semantics. Retests of failed elements are, for
paperwork purposes, considered separate sessions (or sittings).

The ARRL/VE Manual says "The ARRL/VEC charges $6.65 per candidate, per
session." Of course, that was published before the fee increased to $10.

The original poster said they were going to charge for each exam (element),
which is inappropriate.

Rus,
If the antenna is in the attic, I just wouldn't worry too much about grounding, especially for lightning. If the antenna in the attic is hit by lightning, it would have to come through the roof to 'get' it. If the roof is struck by lightning, that antenna and your radios are going to be the least of your worrys!

My feelings have nothing to do with it. There simply are not enough
people who want to eliminate Morse code to matter.

> >A lot of people who matter want to eliminate the Morse code
> *requirement*.
>
> I see. Their opinion determines whether they "matter" or not. Uh huh.

Nope, the number of them is what matters. Tens of thousands of hams
want to eliminate Morse code testing. Less than 100 want to eliminate
Morse code. IMO, of course.

How about a random-length skywire? Put up as much wire as you can. Make it as square as you can. Put it up as high as you can. Run it through the trees and use an insulator and rope at a corner. Let the wire droop some. Don't run it over power lines. Feed it with ladder line. With a good tuner, you'll probably be able to tune it on all bands 160m to 10m. Moderate DX performance on the higher bands, good local coverage on the lower bands. The skywire comes up every couple of months, so search in the archives of DejaNews for more info. 73

1426. TVI HELP!!!!

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-18 03:07:52 UTC
From: "David J. Moge" <n1rzb@mailops.com>
Message-ID: <3a6661e2@excalibur.gbmtech.net>
Source record: 171969

In brief, I have a multi element TV antenna with a amplifier connecting to 4 televisions. The house lot is laid out in such a way that it's very hard to string antennas up with out having them in close proximity to the TV antenna.

At Christmas I found a Six Meter rig under the tree.(MFJ 9406 SSB/CW 10 Watts) which my wife gave me. I put up a dipole to try it out and to my surprise it works quite well. With a antenna tuner I have a 1.3:1 SWR.

My wife hasn't stopped yelling at me sense. Every time I key the mike or try out CW the TV's go blank. I have tried a HI PASS filter but that doesn't do much go at all.
My HF rigs cause no problems at all. I do have a good RF ground

WHAT AM I DOING WRONG??? HELP!!!

Any comments and suggestions would be gratefully appreciated.

Thanks

Me? I'd suggest that the alarm company fix it

OK, so first I'd try to work things out, but I'd want the alarm company to
give its blessing to any mods. They really should RF proof their
installation.
Around here, the ordinances are such that they have to fix it, or put up
with any interferrence they receive. (If the station is clean)

Just wait till I go on 160 with a KW.

Some one in the neighborhood got a scanner for christmas. It has a birdy
right on 446.00 just strong enough to break the squelch. I haven't located
it yet, but it sure is a nuisance.

Sure that isn't 1.6 MHz?

I saw a set of 4 on e-bay a while back. I prefer 6 when duplex on the same antenna. 4 work fine with two antennas. Then again it depends on how much power you run.

I did see a set of 6 at our swap last June, but I had already spent my money on a new HF rig, a UHF/VHF mobile, and an old Henry 2K4. If I'd brought home one more thing, I'd have had to sleep in the dog house and we don't have a dog.

They are "similar" to the "Winchester" series of military plugs. You might
have to modify/replace the socket, but there has to be a way. I have one of
the old Wilsons which is much like the one you have, but as I recall, it
uses an 8, or 10 conductor cable. I had the plug and it has to be around
here *some where* in all the junk <sigh>

Careful with that pressure washer. I can cut 2 X 4s with it on high pressure
(3,300 psi) and yes, the rubber suit is a must. Wear some heavy clothes
under it though. That pressure washer will pick up small stones and throw
them like a bullet! From experience I know that they can really hurt and I
had heavy clothes on under the suit.

It probably goes without saying that a face shield (and goggles) are
mandatory.

A simple hook like cutting bladeon the back of a garden tractor (with a
piece of 3/8 ths tubing down the back makes an excelent ground installer.
Hook the end of the wire to the ground and then you just feed in the wire
off a roll as you drive away. <:-))

If you have a pressure washer you could install the wire down 6 inches (a
bit deep) when it's below freezing <G>

It's a little trolley that rides on the outside of a fixed tower that allows you to mount and work on your antennas at ground level, then raise it back up to the top of the tower. Hazer sells both the mount as well as complete tower systems.

1435. Raised radials vs. longer radiator

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-18 07:06:33 UTC
From: Ken & Mary <kenmary@interpac.net>
Message-ID: <gJw96.4461$d25.28614@newsfeed.slurp.net>
Source record: 171958

I have been studying lots of articles about relative efficiencys of verticals with differend numbers of radials, different heigths of the radials, etc. What I have not found yet is a comparison for a fixed total height. For instance if the top of the vertical could be only 1/8 wavelength above ground (terra firma that is, not the radial system) how would a raised feedpoint and radial system compare to a radial system on the ground. So lets say in my neighborhood I could only get away with a 60 foot vertical with no top hat. What would be better 60 radials at ground level and a full sixty foot radiator, or four radials ten feet up and only a fifty foot radiator?

They have everything to do with it. Whether or not something should be tested or not, and how much testing is "enough" is really just an opinion question - based on feelings. That's not a bad thing.

> There simply are not enough
>people who want to eliminate Morse code to matter.

All it takes is a few in the right places.

You didn't write that there weren't enough to matter. You wrote that nobody who matters wants to eliminate the Morse code. Not the same thing at all.
>
>> >A lot of people who matter want to eliminate the Morse code
>> *requirement*.
>>
>> I see. Their opinion determines whether they "matter" or not. Uh huh.
>
>Nope, the number of them is what matters.

That's not what you wrote.

> Tens of thousands of hams
>want to eliminate Morse code testing.

I don't see that at all. Maybe two, three thousand, max. Hundreds of thousands want to keep it.

> Less than 100 want to eliminate
>Morse code. IMO, of course.

In other words, you don't have any facts.

>> is right there.
>
>There simply are not enough of those people to matter.

Depends on who they are. Do you agree that allowing DSSS on the HF ham bands could seriously disrupt the use of other modes?

Here's an example:

Suppose Station A is using SSB on 20 meters with a 2.5 kHz wide receiver. Station B, running 100 watts, on SSB, is S9+40 dB at Station A. This makes a few kHz of the band unusable by Station A. No big deal.

Now Station B switches to DSSS and spreads his signal evenly over 250 kHz of 20 meters. (Yes, I know it doesn't spread evenly, but to simplify we'll assume even spectral power density). Spreading that S9+40dB signal over 100 times as much spectrum lowers the apparent level at Station A by 100 times - 20 dB. So now Station B is heard by Station A as an S9+20 dB noise source covering 250 kHz of the band. If Station A doesn't have a directional antenna to null out Station B, there's not much that can be done. Noise blanker is of no use.

Even if Station B reduces power by 20 dB - to just 1 watt - Station A has to deal with an S9 noise source. From ONE DSSS station. How many S9+40 dB SSB stations does one hear on 20 when the band is open?

Would you say somebody who thought that the above scenario was not a problem "didn't matter"?

Source record: 171918

(I posted a similar message a few minutes ago, but my line dropped and I don't think it got through.)

I'm putting up a dipole with ladder line feed on the other side of the house. So I need to route it around the house, over downspouts, etc.

Does anyone know of anything that works as a stand-off? (Metal won't do, of course.)

I saw at Agway a standoff for electric fence that you nail to a post, with a clamp arrangement that's wide enough to take ladder line. But they have it only in bright yellow. This might work if I could find it in black, clear, or brown (the color of the house).

Thanks for the help.

I use a home-brewed loop made of 1/4 inch copper pipe. It is mounted about 2.5 m high so that I can tune it manually. In a wooden house or in an open space it works very well but needs to be retuned very often. In an apartament with a lot of wires and some concrete, a ceiling dipole was better. 73,

Assuming this is a 75m antenna, 60' and 60 radials would be
better. Four elevated radials are not all that effective when
they are only .04WL from the ground.

> for 'truth'?

Actually, the CW word for 'truth' is -.-....- ;-)

The "CW is a language" crowd is partially right. Given several centuries of heavy usage and rapid evolution, CW could come up with a unique grammar and syntax with little or no relationship to English.....I think. The process would be something like that going on with sign language where the sentence word order has changed to a postfix subject-object-verb one. But it's easy to see that "CW as a language" is stillborn for a number of reasons. First and foremost, if it loses its one-to-one mapping to English and other established languages, it loses much of its utility as a message relay system. An English-language message submitted on one end of the circuit would probably come out the other end in a substantially different form. Imagine every message having to be translated from English to Navajo and then back to English. It might work fine for artillery firing coordinates but would really lose something on a philosophical treatise. And then there's the economic aspect. It just isn't worth the time to learn and evolve the language when the financial incentives disappear due to technological advances such as teleprinting. Man-months aren't mythical, they're paid for with real dollars and even existential pleasures have costs.

This isn't to discourage the preservation and further development of a unique CW language and culture. Just don't expect my participation, OK?

Exactly what is a half wavelength vertical antenna? What is the general configuration? Why doesn't it need a ground plane or radials? What does its radiation pattern look like?

Is a half wavelength vertical simply an end-fed dipole? Or a dipole configured vertically instead of horizontally? Or both?

I know from recent experience that a half wavelength vertical is not simply an enlarged version of a vertical monopole antenna. My 18-foot wire monopole antenna performed about as well as a 20m Hamstick (and even tuned better) on 20m. I couldn't get this wire to tune at all on 10m. (I have heard that a random wire antenna should be close to an odd multiple of 1/4 of a wavelength.)

>radiator?

Four raised radials up less than 16 feet on 80 are not as good as the
ground mounted solution. Not only that, they introduce the really bad
problem of a step voltage that blows everything away if it gets hit by
lightning. You may not realize it, but even milli-ohms are a huge problem
when 10K amps of RF is involved! I warn you, it's a mess, I know.

There is likely a better one for you that will make everyone happy
including you!

Sixty radials on the ground with a folded monopole at less than 60 feet
will probably be your best bet of all if you cannot get enough top hat up
there to be effective in lengthing the antenna without notice!

A variation on the conical monopole idea, you can effectively shorten the
element length by making it into a long skinny 'loop' and it works just
beautifully, in comparison to what you are suggesting!

Not only that but the 60 radials will do a heck of a lot better at
protecting the site from strikes if they are properly coordinated with
the feed to the system and the ground layout for the shack.

A very interesting solution done this way by Lawrence Behr for WTAW-AM
on 1150Khz here in College Station provided a multi-element full directional
array for night time use here with about 3/4th's the height of the main
256 foot center radiator! There are an additional two towers somewhat
shorter than the main stick! Below the height of the main tower, it didn't
have to be lighted as well. It was the first time I'd been introduced to
the idea of shortened monopoles as decent elements for low band work.

Haven't tried it yet, but the same technique is one I intend to try for
a 160 meter array on only 65 foot towers. There ought to be a magic
configuration of either feeding the free end of the loop on 160 or
grounding it to the tower base with a relay which should get you a
combination shunt fed, gamma matched, 80 meter full sized element, as

well as a monopole 160 element on the same mast. It will result in some shortening of the whole full sized element for 80, due to the expanded element diameter on 80. However, my hunch is that there is a "magic" lashup that will get you both, including a full 160 meter 4 square out of a full sized 80 meter 4 square, if you can solve the 1/8 wave spacing problem.

Further, there ought to be a "spacing of joy" setting even wider than the conventional 65 feet or so on 80, that would give you increased versitiily as to F/B ratio on 80. At at the same time, it would help in getting rid of some of the feed problems associated with 1/8 wave spacing for a 4 square that have been noted elsewhere.

It would be a *HECK* of a lot chaper than a full sized 4 square for 160!

All slated for research here at my QTH, if I ever get the time to do it..

"Starry starry night! ..." Enjoy!

There can be two configurations -- the end-fed Zep, IIRC, is an end fed
half-wave. Make it vertical.....

> Is a half wavelength vertical simply an end-fed dipole? Or a dipole
> configured vertically instead of horizontally? Or both?

The vertical half-wave monopole is a completely different animal. Due
to the ground system of radials if acts as a full-wave dipole, not an
end-fed half-wave dipole.

> I know from recent experience that a half wavelength vertical is not
> simply an enlarged version of a vertical monopole antenna. My 18-foot

Your experience is misleading, due to the very high impedance found at
the feedpoint of a full-wave dipole (half-wave monopole over ground).

A J-Pole, fed the typical way by feeding the two legs of the J, is an
end-fed vertical half-wave with no ground system. Of course, you could
feed a J-Pole at the standard dipole feed point -- the J configuration
is for both tuning and for decoupling the dipole from the coax and the
ground.

AM broadcasters have used half-wave vertical monopoles for years -- they
produce an interesting exercise in the design of tuning networks. The
nicest thing about the halfwave monopole is the high impedance, which
reduces the ground system current, making the antenna more efficient
than one with low feedpoint impedance. But you have to design the
tuning networks to properly handle the voltage produced to make power on
that high impedance -- a completely different problem from the typical
short monopole, which needs current capability instead of voltage
capability.

Hi Richard,

I was raised in Colorado at Fort Kit Carson where they had a mobile cavalry (helicopters). Fort Carson, on the plains, is at an elevation of more than 6000 feet. Getting anywhere in the Rockies requires flight at least at a 10,000 foot elevation (and you could bump into at least 100 mountains) to get to the parks with altitudes ranging 8-10,000 feet. Helicopters don't do very well up there. Or at least the generation of copters (Chinooks - familiar to most who watched TV news of Viet Nam) from the '60's.

One of my favorite haunts is Victor Colorado (birthplace of Lowell Thomas) which is only 20 miles from my parents home in Colorado Springs. Used to be an hour drive, the long way, on a good summer day. Used to be three hours drive, the short way, on a very good summer day. With Winter, don't count on it. That is, until they legalized gambling in Cripple Creek, a neighbor of Victor (just a couple of miles apart) and the gamblers paid the way with road improvements.

1455. Helix antennas for hydrogen line (1420MHz) work

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-18 18:16:37 UTC
From: Ash <abuse@gravitywell.org>
Message-ID: <3A673301.F8915D56@gravitywell.org>
Source record: 171979

Hi
I've been considering using 4 phased Helix antennas instead of a parabolic dish
since they are quite hard to get here in sweden , a 3-5meter dish that is...
I've only used my radioscanner for a couple of years but have been into amateur radio
and satellite work alot during this time and radio communication is my largest interest
since a few years back.
Now I'm tired of playing with weather satellites and such, and is looking to explore what
I'm
really interested in - space. And the waterhole looks like a nice spot to start, I'll be
doing both
hydrogen line work and seti search.
Although I'm an electronics engineer I'm planning on buying most of the stuff ,
from DownEastMicrowave I'm going to buy 1420-144RX downconverter (my scanner only
goes from 10kHz to 1300MHz) and the 1420ULNA <0.4dB NF pre-amp.
Some questions I have about helix's is how directional are they?
Phasing 4 would improve that alot (compared to just one) I guess?
I've seen on some helix designs some use a piece of metal from the last winding and
adjusting it
closer or further from the groundplane, is this necessary for a rx only antenna too?
Is it really possible to replace the dish with helix's? Otherwise I can wait on buying the
downconverter etc.
One other thing, for rx purposes I've been using standard home satellite - low loss 75ohm
cable
(14.5dB loss @ 500MHz compared to RG-214's 18dB loss @ 500MHz (per 100meter) with great
results
for years, and would very much prefer to continue so, will there be much loss jumping from
50 to 75ohm for
downlead only! the 75ohm will still have LNA / downconverter / mmic line amplifier in front
of it,
and on 144mhz the losses are minimal are they not?
I'd really much appreciate valuable thoughts and replies

Regards
Anders Gimseus

I have an NRD-525 with an active antenna hooked to it, indoors. It's a
Stoner Dymek DA 100D. I'm not even sure whether they make it any more,
but it's a good indoor antenna. An Alpha Delta dx shortwave sloper,
outdoors, was about 3db better on the S-meter. I couldn't really tell
you whether the active antenna would be better than a 15-foot long
wire, but I'm satisfied with the Dymek, for what it is...

Source record: 171981

Jason,
A 1/2 wave vertical antenna is an antenna that is 1/2
wave length long. It requires some method of impedance
matching, if fed at one end (impedance > 50 ohms).
A vertical 1/2 wave dipole is a 'normal' 1/2 wave dipole
stood on one end. It's a 1/2 wave vertical antenna fed in
the center. It's input impedance should be about the same
as a horizontal dipole.
Random wire antennas require some method of impedance
matching, the simplest probably being a 'tuner'. The range
of impedances the tuner will handle is the determining factor.
How well the random wire antenna radiates is a completely
different story, and depends on all the 'usual' variables like
height, length, oreintation, gremlins, etc.

Jason, AG4DG wrote:
"Is a half wavelength vertical simply an end-fed dipole?"

Feedpoint, center or end, should have no effect on radiation.

A vertical antenna fed against ground is part of a complete series load circuit which includes radiation resistance (the work output) and loss resistance. The same current flows through the desired load resistance and the undesired loss resistance. The power delivered to each is proportional to its resistance (current squared times the resistance). The conducting material in the antenna should have low resistance. Most of the resistance is probably in the ground system.

Say the ground loss is a few ohms. A quarter-wave vertical may have a radiation resistance near 30 ohms. A few ohms loss may be noticeable, but not notorious.

A half-wave vertical may have a radiation resistance near 800 ohms. A few ohms loss is likely hard to detect.

If ground loss were 30 ohms, about half the power fed to the vertical quarter-wave antenna would be lost in the ground. The loss in power fed to the vertical half-wave antenna would be measurable, but probably not notable.

Impedance is not the only advantage of the half-wave vertical antenna. The half-wave antenna concentrates radiation towards the horizon and this produces more millivolts per meter at a distance of one mile from the antenna near the ground as a result of antenna gain. This adds to more millivolts from having less loss in the ground system around the antenna.

Best regards, Richard Harrison, KB5WZI

1459. Recommend an Active Indoor Antenna for Short Wave?

Newsgroup: rec.radio.amateur.antenna

Yep -- its is a dipole stood on end. It can be fed anywhere provided the impedance is matched. For end fed the Z is very high so a matching network is required -- like the black box on the bottom of the Cushcraft half wave antennas or design a mathing line. It can be center fed (72 ohms) but best run the feed line perpendicular to the vertical radiator, I have done this on a 10M vertical -- works very well.

Cushcraft claims (and is the usual explanation for same) that because it is fed at a high impedance point -- and ground is a low Z point losses are low and -- no radials required, although some claim a ground screen below the antenna (not connected to it, will improve performance). Radiation pattern is claimed as low angle - I've seen 15 - 20 degree claims, but check ON4UN's book on Low Band DXing for these antennas -- varies as several factors. Don't make a radial array for the Cushcraft or Hy-Gain half wave verticals -- messes up the antenna - so sez Cushcraft and me -- I've tried it -- doesn't work.

Do they work -- yep they do -- I've worked a lot DX with my R5 and R-7000. Would rather have a tower or beam or even a dipole at 70 + feet but HOA sez no to that.

Tuning an antenna -- the Antenna Analyzers will tell all. Great device.

OK, first some general comments: A halfwave vertical is a linear antenna with a vertical element half a wavelength long. That would generally imply a half-wave resonance, but you don't have to use it at resonance. You can feed it in the center, off-center, or at the end. If you feed it at the end, you must have a return path (e.g. counterpoise or ground plane) of SOME sort for the current from the generator. If you feed it at the center, it may be a challenge to find a way to get the transmission line to it while properly decoupling it from the transmission line. The current distribution will be similar to what you see on a horizontal dipole, though if it's over ground, there will be some skewing because of the ground. If it's resonant, the current distribution will be nearly independent of where you feed it along its length. In freespace, it will have a pattern just like a horizontal dipole; after all, in freespace it gets hard to tell "horizontal" from "vertical". Over a ground plane, you have the effects of the image on the other side of the plane, and the pattern's vertical shape will depend on how far it is off the ground plane. In azimuth, the pattern will be omnidirectional to the extent the antenna's environment is symmetrical.

Specifics: Sounds like you are trying to feed one against a set of radials. That will work, but at resonance the impedance will be rather high. If you use a large effective wire diameter, the impedance will be significantly lower, without greatly affecting the impedance of the same antenna as a quarter wave on half the frequency. You might try a set of four parallel vertical wires arranged at the corners of a square about a foot on a side. A foot or so above the feedpoint, let the wires angle toward the feedpoint, forming an inverted pyramid at the base of the antenna. That should make the antenna much easier to feed at its half-wave resonance...in fact, the half-wave resonance will drop to a much lower frequency, not so terribly far from 15 meters, and be a few hundered ohms instead of thousands of ohms; and at 10 meters, it will be somewhat reactive but still a low impedance, in the low hundreds of ohms. I'm sure Reg's site has a program for this, and the demo version of EZNec will probably handle it well too.

Cheers,
Tom

Hi Richard,

But by aircraft do you mean helicopters? Fort Carson was also the site of the Mountain Forces Team, and they did not typically operate with helicopters even though they were available. As I understood it at the time, altitude was the prohibitive element.

1. SWR doesn't tell you anything about an antenna's performance. All it tells you is how close the feedpoint impedance of the antenna is to the rig coupled to it. And since you're using a tuner, what you're measuring is simply the match between the tuner and the rig.

2. Neither one of these antennas has an ideal isotropic radiation pattern, and the proximity to the house didn't help much either. No doubt neither antenna was performing in an ideal manner. But the hamstick comes a lot closer to having a useful and predictable radiation pattern.

Where did you put the high pass filter? The best place would be before
the input to the amp. Since the high pass filter is likely intended to
pass channel 2, six meters would not be very far down the skirt. The
typical filters are not very sharp.Cascading filters or using one with
a sharper curve could help. Also some (most) of the consumer amps are
not very good. Do you really need the amp?

Well from my experience that is about par for the course with dipoles
that low in relation to wavelength. I recently put up a 80 meter dipole
only 20 feet off the ground. At resonance it had a resistance of 20
ohms, for a 2.5:1 match. Obviously ,raising the antenna would have been
the best choice, but was not practical at my location. I put an Amidon
4:1 step down balun on it and brought the resistance up to 80 ohms and
fed it with 75 ohm coax. I suppose I could go add a 1.5:1 un/un and get
it better, but I just let the tuner make up the difference. If you have
access to an MFJ 259 or something similar, you would probably find that
at resonance you are at about 25 ohms resistance.

The SWR could be about normal. You did not state if you only measuered the swr at one frequency or if you checked several points to about 100 khz above and below 3953. Uaually you are using a 50 ohm line with a 70 ohm antenna for a swr of 1.5 . The height of the antenna above ground will have a very large effect on the inpeadance of the antenna. It will probably be far from 70 ohms.

Not sure of the receiving problem. Do you have anything to compair the receiver to ?
My 80 meter antenna is on;y up about 20 feet and it seems to work ok. Not the greatest but it is so low that most of the signal is going up and that makes it work well for short distances, up to say about 300 to 500 miles.

My computer system radiates RF and I cannot use my HF rig when it is on.
Radiated RF is a lot harder to snuff than conducted RF. I suspect most
of mine comes from my large cheap monitor.

Yep - IF it was available and working. Two more big "ifs".

>Should ham radio be used for an
>emergency call, SSB would allow the physician to rid himself of one or
>more intermediaries to consult directly with those closest to the
>situation.

Yep - IF SSB were available, and propagation good enough to permit decent copy
both ways. Two more big "ifs".

That's eight big "ifs", so far. Most of the time, all eight would be sure bets.
But not always.

About 3 or 4 years ago, western New York State and parts of Ontario and Quebec
were hit with ice storms. The storms were so bad that even the rugged power and
communication lines of that area began to fail under the ice. Roads were
closed, airports were closed, power was off in many areas, communication was a
mess. Ham radio did some much-needed public service work, helping out with

communications. Most of the stuff was VHF-FM local work - but a lot was also handled on HF because the distances and terrain of WNY are not the best for good VHF coverage.

To add to the problems, many of the stations were on emergency power and jury-rigged antennas. Worse, radio conditions were awful. Morse was used in many cases because SSB just couldn't make it through the auroral noise.

Were any lives saved? I don't know. But I used to live up there, and winter in western New York State is as bad as it gets anywhere in the lower 48.

So a similar situation could happen again.
>
>The Colorado cure is an historic human interest story, but irrelevant to
>Morse testing or antennas.

Who is talking about Morse testing? Not me. We're stuck with the present system until the treaty changes.

I was challenged by a skeptic to come up with examples where Morse was used by hams on the HF ham bands to save human lives. So I did - is that not allowed?

The relevant Morse TESTING questions in all this are: "What are the chances that a ham will meet up with a communications emergency requiring the use of Morse?" and "Are those chances high enough to justify a Morse test for all hams?" I've never claimed the chances of such a situation were high. Nor have I claimed that they were high enough to make Morse testing mandatory. Look up my posts - you won't find any such claim.

All it was is a true story of how hams using Morse saved a life. Guess that sort of thing is electropolitically incorrect these days.

I found on several installations that running an external shield over
the video cable rom the computer to the monitor with a ground to the
station ground works wonders.
My noise level went from basically unusable to unnoticeable.

The shield is tied to the connector metal on both ends.
I used a large braid but tin foil might work as well.

I once bought a nice high end computer to run my station. Tried in vain to get this 633MHz computer to stop generating RFI. Ended up using an "old" abandoned 90 MHz computer as my shack computer. It didn't generate any detectable HF interference. Monitor,keyboard and mouse remained the same in both cases.

What you need to look for is antennas. The computer itself, being fairly small and hopefully reasonably well shielded, isn't a very effective HF radiator. But the various wires connected to it are. Even if your surge suppressor is very good, you still have the whole length of the power cable between the computer and surge suppressor to act as a radiating antenna.

I'd suggest beginning by disconnecting everything you can from the computer -- printer, speakers, monitor, keyboard, mouse, and so forth, and see if the noise is still intolerable. If it is, try winding the power cord into a coil of a few inches diameter. If that doesn't work, try a few clip-on ferrite cores on the power cord right next to the computer. Hopefully, that'll clean things up enough that you can go to step 2, which is to connect things back up one at a time. When you find a radiator, wind its cable through a ferrite toroid with 5 - 10 turns if possible. This will give as much impedance as about 25 - 100 clip on cores. If you can't wind the cable through a toroid, use several clip on cores as close to the computer as you can get them. You might run into a combination of computer and closeness to your antenna where you won't be able to solve the problem without replacing the computer with a better shielded model. But chances are that the following steps will at least help a lot.

If all the other suggestions fail, you might want to try the MFJ 1026 Noise Cancellation unit. Not a cheap solution, but very effective for RFI generated within the shack. I use it to null out RFI coming from a TV set. I have virtually no RFI from my 233 MHz PC, sitting beside the rig.

Hi Cecil,

This is the problem I think was alluded to when I was told helicopters
weren't typically used in the rockies. They can fly at 10,000+ feet
because of the lift from forward motion; but the air is so thin that
their lift capacity from a ground launch is severely hampered. In
other words you can fly there, you can land there, and you can feed
quarters into the parking meter forever after. However, these were
Chinooks, not today's medivacs. They were designed for heavy lift
capacity and were perhaps considered unusable for their mission
purpose when it came to the high country.

This of course does not preclude a flight in to pick up a person
(rather than a howitzer which I observed frequently) - but even here
the mission of the Mountain Team was heavily rescue oriented and yet I
never heard of a helicopter operation.

There may be times when using a radio out of its "type accepted" band is probably not all that offensive in spirit or practice even if technically against the letter of the law. (e.g. marine use where no harmful interference is involved). But using the FT-50 for FRS is not one of those times.

The deviation of the FT-50 is wider than that of the FRS radios. So when using the FT-50 on that band, you are not only transmitting at higher power than the FRS, but run the risk of splattering onto adjacent channels creating harmful interference.

Bill

Hmmm. I know a lot of those guys. I ran exams just down the river from
them in Aurora. In fact, the guy that started the testing group up there
years ago and I were both with DeVry VEC originally. I can't remember
callsigns, since I've moved, but there must have been some turnover that
leaves some uninformed VEs, because the guy I know wouldn't do that or
train his people to do that. Sorry.

> I really don't have anything to complain about...

Yes you do. You were prepared for an exam and an incorrect
interpretation by a team that should know better kept you from taking
the exam when you were ready. Although you might not get any
satisfaction, they need to be made aware of the problem so it doesn't
happen again to someone else.

Mike and Cecil,

Thanks for your responses, I plan on using whatever vertical I settle on, on 160, 80/75, and 40 meters. I live on a hill, not the top, with a beautiful view of Hilo Bay and a really good shot towards North America, and would like to have a decent signal there. My neighbors up the hill have an equal or better view that I'm sure they don't want to have messed up with my antenna(s). (Of course to me and you it would be a thing of beauty) I figure a vertical with a plain, straight top section, and no top hat "wheel" or other similar visually large object, may be acceptable, especially if any guying is low enough that it only interferes with their veiw of rooftops and trees. If only a single slender spike sticks up in front of their view of the ocean and the horizon I think I'll get away with it. As for the higher bands, eventually I'd like to have a motorized tubular crank-up that's only up after dark.

Geez Tom a Superradio AND a select a tenna? You must be listening to china with that setup already. I have a SuperradioIII myself (my favorite radio) and typically listen to AM stations from large cities on the east coast with the stock antenna. Charlotte NC, Louiville, New York City, Chicago and Cincinati come in stable like they are next door, along with a few Canadian stations depending on how the radio is turned. I am in Washington DC. I have heard the CCradio advertised, personally it sounds like an overpriced Sangean model to me. I suppose the digital tuning would help if you are trying to seperate the stations, but personally I prefer the tone of the superradio to any of my other portables. I have an 18 year old Uniden CR-2021 digital that picks stations out a little better than the superradio, but it sounds tinny and suffers from some SW interference-only good for SW. Theres a big price difference too, you can get a Superradio at Ames or Kmart for 45 bucks on sale, the CCradio (actually a Sangean)Is up around $120.

1498. Anyone have experience with a commercial QFH antenna ?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-19 03:30:24 UTC
From: Pervert_Extraordinair <valued_customer1@att.com>
Message-ID: <3A67B4D0.468E9B23@att.com>

I'm using an attic mount homebrew QFH antenna for
weather satellite APT reception.

I've decided to move the QFH from the attic to the outside,
so I'm considering my options. One of the options is to
purchase a commercial QFH. While these are quite expensive
($~250) they do come with an integral amplifier which would
certainly not hurt.

Anyone have any personal experience with any commercial suppliers?
I've only found a few for sale. The following from Norther Video
Graphics is one: http://www.nvgweather.com/page2.html

Any suggestions/comment would be appreciated.

Yes,they are supposed to be.

These guys seemed pretty
> confident that they could charge $10 per exam

By the authorizing law they are not supposed to charge beyond recouping
their expenses, unless it has changed since I was active. I understand
that the FCC has stropped setting the mandatory fee, so the VEC under
which they operate should be doing it.

FCC never did stipulate nor specify what constituted an expense, they
just said that the expense must be related to the testing and that a
record of all monies received and disbursed be maintained.
The fee receipts were always split by the VEC (ARRL here) and the VE
team. The VEC sets the details of he split.

The usual standard approach here is to load evey cable coming out of the
computer up with ferrite beads right at the back of the computer.
>
Check for RFI on any VHF bands you use. I had an external modem which didn't
make a peep on the low bands but it obliterated 2m. The only way I could shut it
up was to toss it into the dumpster.

Yes, but they're expensive and not common. So you're pretty much stuck with using the clip on cores for the printer cable. There are some other things you could do, such as winding a few turns on a ferrite rod, or on a discarded TV yoke core. But it would take several turns on a rod to equal a single snap-on core (because of the air in the rod's magnetic path). The yoke would work ok if you can put it back together very carefully to avoid even the tiniest air gap where the halves meet. A large U-I core pair would work, too, but you don't find them at most flea markets -- especially large ones.

Incidentally, the best ferrites to use for this application are the high-permeability, "low frequency" ferrites, such as Amidon/Fair-Rite 70 series. Type 43, which has a bit lower permeability, also works well and is available in a variety of sizes. It's marketed for this purpose, so a lot of the snap on cores are this type of ferrite or similar.

Richard Clark wrote:
" - but even here the mission of the Mountain Team was heavily rescue oriented and yet I never heard of a helicopter operation."

Our aviation department`s practices were extremely conservative. It`s how they maintained an outstanding safety record. We had many helicopters, and fixed-wing aircraft from single-engine Cessnas to BAC-111 jet airliners. In Bolivia, we only operated fixed-wing aircraft because of economics and perhaps the service ceiling problem. Our aviation department insisted on twin-engined aircraft, or aircraft with more than two engines, which could carry a full load without one engine and still clear Ilimani, Bolivia`s tallest peak. When a Cessna couldn`t meet the requrement, it was quickly replaced with a similar Beech that could.

I`ve spent the day above the soup over Bolivia looking for a hole to drop through so we could find a landing spot. We overflew our destination several hundred miles before finding a hole. Had we not had the excess altitude capability we would have been in the soup. That`s not so bad, if you know you are higher than any of the mountain peaks.

Had we needed to evacuate someone from the andes, we would have contracted with a helicopter operator skilled in such operations. With over 30 company aircraft, we still often contracted with other aircraft operators for economy, convenience, or to do a job they could handle better than we could. But, if we couldn`t come up with a contractor, we would have sent a company aircraft even if the operation didn`t fit the usual company policy. It would be dispatched only in weather clear and stable enough to be sure it would be very unlikely to be flying blind into any mountains. Many times our company aircraft were dispatched for medical evacuation and transport not only for our employees and contractors, but as a humanitarian good deed for people we had hardly heard of.

In the early days we only had Bell helicopters, but in later years, the MBB (Boelkow) became the favorite (I didn`t like the way that bird shakes when it hovers close to the ground, but the pilots like it).

Helicopters can even fly pretty high in thin air. They have to sacrifice load capacity. I`ve been aboard for sight-seeing tours in the rockies. I`ve seen video footage from them and of them from high in the andes and other mountains. but I don`t know what the elevations were in the 1935 medical information relay story. For all I know the elevations are above the service ceiling of today`s helicopters, but that would surprise me.

Best regards, Richard Harrison, KB5WZI

I know a ham in PA who restored a Telrex 3el (?) 40. I don't know which model. He had problems with a broken or deteriorated phenolic insulator. Does your Telrex have the through-the-boom elements with the phenolic insulator sleeves? My friend bought fiberglass tubing stock for a replacement. He did have to get a shop to turn them down just a bit in OD, if I remember right (or was it ID?) Anyway, worksfine/lasts a long time, and he is glad he took the trouble to repair his. 73, David K3KY

Cecil, W6RCA wrote:
"I once took off from Bogata in August. (Heat thins the air.) When the plane ran off the end of the runway it dropped like a rock. Luckily, it dropped into a valley."

The airport at La Paz, Bolivia is situated the same way. The airport is up on the Altiplano high above the City of La Paz, which is down in the valley. The runway ends at the shear precipice. I`ve had the roll off the cliff experience with Lloyd Aereo Boliviano (LAB). Fortunately, the drop produced emough speed to take flight. It can be very exciting.

I had another LAB experience. Two aborted take off attempts caused us to board and deboard twice for attemped repairs. I saw guys in monkey-suits banging on engine parts with big hammers.

On the third boarding, I noticed the first cabin attendent I saw was a new face. So I asked her why I hadn`t seen her on the previous take off attempts. She replied that all the crew was new because the previous crew had refused to fly the plane. I said, "Thank you lady. That is good enough for me and I`ll be leaving too." When I deboarded, all the Bolivians seeing the gringo leave decided to follow suit, and the flight was cancelled.

Best regards, Richard Harrison, KB5WZI

1509. FCC proposal for new Amateur "Colt" License Class

Newsgroup: rec.radio.amateur.antenna
Date: 2001-01-19 06:52:23 UTC
From: Stewart R Teaze <HORSESHOE7@prodigy.net>
Message-ID: <948o9h$4mg4$1@newssvr05-en0.news.prodigy.com>
Source record: 171882
Cross-posted to: rec.radio.amateur.policy,rec.radio.amateur.antenna,alt.radio.family,rec.radio.cb,rec.radio.amateur.digital.misc

The rapidly-expanding Family Radio Service has exposed millions of young people to the world
of radio communications. But now, where is a young kid to go who has is interested in experimenting
with radios and get more range than the typical 1/2 mile of FRS? MURS might help a bit(if Motorola doesn't
get their way), but you know that a growing mind is eventually going to want more than just this. GMRS
doesn't have the resources, and is not a service that was created to foster experimentation. Like it or not,
the typical young person ends up cutting his radio experimention teeth in the Citizen's Band service, because
there isn't a reasonable entry-level ham license for kids(it is even worse now after restructuring, what with the
elimination of the Novice Class).

Everyday now the USA is falling further and further behind Europe and Japan in the wireless communications
race. As hams, it is time we make an effort to insure that our young people are provided with the proper
environment, incentives, and role models to properly learn radio communications techniques and etiquette.
It is time for hams to stop complaining, step up to the plate, and take an active role in seeing that our bright,
young technical minds are being taught properly.

As a result of this, I have reworked the Communicator entry-level license proposal I submitted to the FCC last year,
and I will now be proposing a new entry-level Amateur Radio class known as the "Colt" class. I submit a draft
of the proposal for your review below. Please keep in mind that the future of American involvement in wireless
communications development depends on us to properly encourage and teach tomorrow's experimenters, operators,
technicians, and engineers...

****
Proposal to FCC to institute an introductory-level "Colt" license class in the Amateur Radio Service - REV A

In the late 1980's and early 1990's when the current Amateur Radio Service Technician Class license was conceived and implemented, it was
an appropriate alternate introductory license class. However, due to the recent elimination of the Novice Class license, and as a result of improving

technology; the Technician Class license no longer serves well as the only introductory license, as it is doing poorly in drawing young members into the Service. As a result of license restructuring, it is now actually harder for young people to obtain an Amateur license than it was before restructuring.

In this critical era of global competition, especially in the wireless communications arena, it is essential that we provide a means for properly educating our young people in RF communications operation and theory.
